The sagacity of the poet here,-that strange sagacity which seems so nearly akin to the prophetic spirit,-suggests in this noble passage the true reading of the enigma. The appearance of man upon the scene of being constitutes a new era in creation; the operations of a new instinct come into play,-that instinct which anticipates a life after the grave, and reposes in implicit faith upon a God alike just and good, who is the pledged "rewarder of all who diligently seek Him." And in looking along the long line of being,-ever rising in the scale from higher to yet higher manifestations. or abroad on the lower animals, whom instinct never deceives,-can we hold that man, immeasurably higher in his place and infinitely higher in his hopes and aspirations, than all that ever went before him, should be, notwithstanding, the one grand error in creation, -the one painful worker, in the midst of present trouble, for a state into which he is never to enter,-the befooled expectant of a happy future, which hé is never to see ? Assuredly no. He who keeps faith with all his humbler creatures,-who gives to even the bee and the dormouse the winter for which they prepare,-will to a certainty not break faith with man,-with man, alike the deputed lord of the present creation, and the chosen heir of all the future. We have been looking abroad on the old geologic burying-grounds, and deciphering the strange inscriptions on their tombs; but there are other buryinggrounds, and other tombs,-solitary church-yards among the hills, where the dust of the martyrs lies, and tombs that rise over the ashes of the wise and good; nor are there awanting, on even the monuments of the perished races, frequent hieroglyphics, and symbols of high meaning, which darkly intimate to us, that while their burial yards contain but the debris of the past, we are to regard the others as charged with the sown seed of the future."

In conclusion, it should be stated that the value of the explanatory portions of the present work is much increased by the addition of numerous, well-executed engravings. Most of these, however, greet us with a strangely familiar aspect. The greater number appeared originally in a little elementary work in French by Beudant, and in the "Cours de Paléontologie," of Alcide d'Orbigny; but they have done duty since the epoch of their first appearance, in several English and German works; an ongst others, oddly enough—when considered in connexion with the present book—in that work of very opposite tendencies, the "Lehrbuch" of Carl Vogt. We must except however, the illustrations of the last two lectures—" The Fossil Floras of Scotland"—which appear to be original. These lectures : in a scientific point of view the most important in the volume, scarcely belong to the general plan of the work. and hence we have not alluded to them in our review. We trust, however, to give some extracts from them in a future number of the Journal.

E.J C.

The Canada Educational Directory and Calendar, for 1857-8; containing an account of the Schools, Colleges, and Universities; the Professions; Scientific and Literary Institutions; Decisions of the Courts on School Questions, &c., &c. Edited by Thomas Hodgins, B.A. Toronto: Maclear & Co., 1857.

It is no discreditable or unsatisfactory evidence of the rapid progress which Canada is making in the all-important step of providing for the intellectual growth of the province, that such a work as this can be issued with a reasonable prospect of its success as a trading speculation. The number of those interested in educational questions must be considerable, before such could be the case, and to all such the "Canada Educational Directory" can be confidently recommended. The courses of study and requirements for the various examinations in Schools and Colleges, for Masterships in Common and Grammar Schools, for Degrees in Universities, admission as Students or Barristers-at-Law, Surveyors, &c., are here set forth in an exceedingly convenient and accessible form. Lists are also given of the Office-Bearers, Professors, Teachers, Graduates, &c., with a brief, and on the whole impartial notice of the various constitutions of the very diverse educational institutions of the province. Here and there remarks occur reminding us of the conflicting opinions which prevent a perfect union among all the sincere promoters of a liberal education throughout the province; and one or two notes and comments scarcely correspond with the character of the work ; but the editor deserves credit for the general aim at impartiality apparent throughout. In some cases information has been withheld, and in the whole compilation considerable labour must have been incurred to secure the accuracy in minute details, without which the object aimed at in its publication would be defeated.

In addition to the varied contents, thus summarily noticed, there is also a useful department, embracing the principal Scientific and Literary Associations of the province, which already begin to assume a very creditable aspect. Unpretending as this work is, it will be valuable to the historian of Cauada, hereafter, when the harvest of this good seed-time is beginning to be reaped. We wish the work all success, and hope to see it established as a regular annual publication, improving yearly with the progress it records.

D. W.

Indigenous Races of the Earth; or new chopters of Ethnological Inquiry; including Monographs on special departments of Philology, Iconography, Cranioscopy, Palæontology, Pathology, Archæology, Comparative Geography, and Natural History: contributed by Alfred Maury, Bibliothécaire de l'Institut de France, &c. &c., Francis Pulszky, of Lubocz and Cselfalva, Fellow of the Hungarian Academy, &c. &c., and J. Aitkin Meigs, M. D., Projessor of the Institutes of Medicine in the Philadelphia College of Medicine, &c. &c.,; presenting fresh investigations, documents, and materials. By J. C. Nott, M.D., and Geo. R. Gliddon, authors of "Types of Mankind." Philadelphia: J. B. Lippincott & Co., 1857.

Such is the title, in a greatly condensed form, of the new work by the authors of the "Types of Mankind;" wherein they have carried out still further even, than in their former joint production, the cooperative system, applied of old so effectively in a very different branch of English literature; when Shakespeare, Jonson, Beaumont, Fletcher, and Massinger, conjointly produced works which defy the modern critic to apportion to each the product of his gifted pen. No such homogenous character, however, marks the modern literary edifice. Each independent labourer carves his own masonry, inscribes it with his mark, and places it, finished, at the disposal of the master-builder, to be harmonised as chance or fortune shall direct, with the stones that are ready to be built with it into the superstructure. The coherence in fact, is little more than such as pertains to the various independent articles which go to make up a cyclopædia, where absolute concurrence in opinions, or even in statement of facts, is not indispensable; while the whole makes

a bulky quarto volume, which, as it has just come to hand as these sheets are passing through the press, we can only notice very cursorily. And glancing first at that which comes last in the order of arrangement, the special chapters devoted to the controversial theme of "the Monogenists and Polygenists," or in simple words : the unity, or the diversity of the human race, as the descendants of one, or of several pairs : we cannot but regret the form in which it is here put forth, as calculated only to excite unnecessary prejudices against the whole inquiry. Notwithstanding the vehemence of its offensive and defensive warfare against all who venture to maintain their literal interpretation, in simple faith, of the words of their Eng lish Bible, that God " hath made of one blood all nation of men :" the author himself confesses that whilst according to his present opinions, "the reasonings in favour of the diversity view preponderate greatly over those against it. he does not, nevertheless, hold the latter to be, as yet, absolutely proven." Such being the uncertainty even in the mind of the boldest and most aggressive champion in the cause of a diversity of origin for the human race, we feel assured that the great majority of Ethnologists must deplore with us, the premature dragging into the arena of theological controversy of a science which is still in its mere infancy; has its data to accumulate, its first principles to determine, and even a commonly recognized nomenclature and termonology to agree upon; and is therefore totally unprepared to buckle on the armour fitted for offensive warfare. What faith can the simple learner be expected to repose, for example, in arguments based on Egyptian chronology, when no two of its authorities can be got to agree on its dates. Within a brief interval of five years, the era of Menes alone shifted back and forward over a range of variations differing by upwards of two thousand two hundred years. Since then it has shown no greater tendency towards a stable equilibrium. Bunsen, indeed, it would seem, from private information of his most recent views just received, (p. 587,) makes of Menes' Egyptian reign (B.C. 3623,) quite a modern era, and starting with the origin of mankind 20,000 years before Christ (!) he gives us an Arian migration circa B.C. 11.000 : an Egyptian Republic, B.C. 10,000 ; a Theban Hierarchy B.C. 7,231 ; and an elective monarch extending from the precise date, B.C. 5,413 to the very year in which Menes-the first of us moderns-united Egypt under his single sceptre, exactly 5480 years ago! In some comprehensive ante-historic eras. Mr. Gliddon such fully "Egypt," concurs. he remarks in summing up an ideal VOL. IL.-O.

analogy, (p. 557,) "oldest of historical lands, representing therefore but the 'middle ages,' of mankind's development upon earth, typified by our cosmic man, arrived at one third of the 'three score and ten years' imagined by Hebrew writers to be the average of post-mosaic human longevity, it follows that at the third dynasty, say 5300 years ago, the Egyptians at least, among, very likely, other oriental nations whose annals are lost, had long before passed through their periods of adolesence, childhood, and infancy." Yet the bewildered student who looks in vain for some terra firma, pretending not (as even the best educated of scholars or students of natural science may surely be allowed, without charge of unbecoming ignorance.) to judge for himself of Turin papyri, petroglyphic inscriptions, Apis-periods, and disputed dynasties, is not to suppose that he may ask for any definite chronology on which learned Egyptologers are agreed. The very Chevalier Bunsen, whose views are quoted approvingly on p. 587, as newly received, and interesting matter "in support of preceding remarks," is referred to on p. 487, before such new matters had come to hand, in these terms :-which disclose to us the the pregnant fact that even Mr. Gliddon is now reserving his own final decision, till the forthcoming of the long promised "Book of Kings" of Lepsius : "until the appearance of which, I have consistently maintained since 1844, no professed system of Egyptian chronology can, in the very nature of human things, pessess solid or durable claims to attention : such as have recently appeared, worthy of respect, being either like M. Brunet de Presle's, a re-examination of the classical sources ; or else like Chev. Bunsen's second volume, a labyrinth of arithmetical adjustments, satisfactory to no one but their learned calculator: or again, similar to the useful but very piece meal coverings of a skeleton chronology, by M. Brugsch, who, in the main, agrees with the time-measurements previously laid down by Lepsius; or finally, ingenious attempts at unsettling that which had been generally agreed upon, by Champollionists, through M. Poitevin's attorney-like process of detecting some supposititious flaw in the indictment. For myself, therefore, as before stated, I have no more precise Egyptian chronology to offer than that already sketched in Types of Mankind; and having waited some twelve years for Lepsius, it is small hardship to extend one's patience a few months longer."

But what, meanwhile, is the inquiring student to turn to, while waiting till the luminaries of Egyptian chronology shall have made up their minds what is to be believed? There is the Geological

department, with its fossil human remains :-- fossil and humatile, to use a new word coined to designate that which has been accidentally deposited in the earth, in contradistinction either to the true fossil or to purposed sepulture. Here at first sight then, is a startling array of facts :- the Guadaloupe skeletons : the cave remains, found along with the ursus spelæus, extinct rhinoceros, elephant, &c., at Gard, Torbay, &c.; the Floridian human jaws and foot, "embedded in a conglomerate at least 10,000 years old;" and finally, the celebrated os innominatum, found near Natchez, on the Mississippi, below the skeleton of a megalonyx and other extinct quadrupeds. These and other instances quoted more extensively, and we may add more confidently, in the Types of Mankind, than in this later work, would seem at first sight to make up for any dubiety arising from the disagreement among Egyptian chronologers. But when the honest inquirer turns here for guidance to the authorities in science. Mantell tells him the Guadaloupe skeletons are quite modern : Sedgwick, Buckland, and Hugh Miller, are agreed as to the recentness of the human cave bones; Lyell gives the weight of his testimony against any argument based on the Natchez os innominatum : and in fine, the geological argument for palæozoic human remains is sought for in vain in the accredited text books of geological science

The like argument applies to the Archaeological evidence. The fint implements, pottery, &c., found in British caves, where positive evidences of sepulture entirely remove them from being classed as contemporaneous with the embedded remains of any but the most recent extinct mammals, have even been found accompanied with specimens of art-Roman and other-belonging to the Christian era; and as to M. Boucher de Perthes': "Antiquités Celtiques et Antédiluviennes," largely built upon in the Types of Mankind, pp. 353-372, and here again referred to, with further corroboration from later investigations of Dr. Rigollot: we can only say if the "antediluvian remains of art," of the latter explorer, are no better than those of the former, they will carry even less conviction to the minds o Archæologists, than the quoted examples of "fossil human remains" appear to have done to Geologists. We got hold of M. Boucher de Perthes' work years ago, when engaged in investigations which would have made us gladly welcome his conclusions, had his premises been even plausible; and had he not accompanied his enthusiastic descriptions with his honest matter-of-fact illustrations, we should have been sorely puzzled to reject his "figures et symbols de la période antédiluvienne," his "haches celtique, instrumens en pierre"

and other specimens of "*industrie primitive*;" but having examined his eighty engraved plates, with hundreds of figured examples, we venture to say that any man may provide himself, blindfold, with equally good evidence of antediluvian and preadamite art, in the first heap of broken stones he stumbles over!

And what, let us now ask, is the position of this science of Ethnology, which undertakes to dictate to all older ologies? It is, as we have said, in its veriest infancy. Ethnologists are not as yet agreed upon the simplest common terms. Scarcely two of them can be warranted to mean the same thing when they employ such simple words as race, family, or species ; to say nothing of Arian, Touranian, Mongolian, Berber, and the like, once more discussed here. The relative importance of philological, physiological, and archæological modes of investigation are so little determined, that the, craniologist slights the philologer, and the linguist in turn scorns the cranioscopist. Is such then a time for the students of this young and deeply important science to waste their energies in bootless controversies on questions, which, if truth were once established on a commonly recognised scientific basis, would vanish like the mists of dawn, before the sun? Such is the utter want of any conformity in the use of a received terminology, that in this very work, we find the term "*Caucasian*" employed by M. Maury (p. 84,) as equivalent to what he calls "the white race," and again by Dr. Meigs, (pp. 219-257,) confessedly unscientifically, as the most convenient one available under which to group such a miscellany as Norwegians, Fins, Germans, English, Irish Celts, Sclaves, Jews, Egyptian Fellahs, Thuggs, &c. Mr. Gliddon again has his own views on it (p. 563,) as a term of mystifying vagueness in Ethnography; or with the Count de Rechberg (p.p. 624, 625,) restores it to the only definite meaning it seems capable of, as "the highest type" among the multiform inhabitants of Mount Caucasus. What the present recognized scientific value of the word is, we defy any one to say. So with "Pelasgian"-if possible, a still looser and more debateable term. "Dr. Morton," according to Dr. Meigs, " used the term Pelasgic too comprehensively. The Circassians, Armenians, and Persians, should not be placed in this group." In his estimation, however, it appears that, "Ancient Romans, Greeks, Affghans, and Græco-Egyptians," all properly class as Pelasgic. Dr. Latham on the contrary, classes both Persians and Affghans under one "Persian Stock;" the modern Greek he would agree with Mr. Gliddon in recognizing as, to a great extent, Sclavonic. The seemingly

simple term Roman again, as included in the so-called Pelasgic Race, -what is its value or significance? It does not embrace the Etruscans: does it include Oscans, Umbrians, Sabines, Samnites? Does it apply to all Ancient Italians south of the Tiber, extending even to Magna Græcia? Or is it, after all only a political term, having no precise ethnographic value at all, but making of every Roman legionary a Roman, just as we may call, if we please, an Indian sepoy a British soldier? Such, as a specimen, is an analysis of the details of this Pelasgic classification according to recognised authorities. But what does the term itself signify? If we turn to Grote, the one conclusion he is sure about is that the Pelasgi were non-Hellenic; adding somewhat pungently an application of the comment of Herodotus on old Egyptian theories, to those who pretend to be wise above what is written, in this :- that "the man who carries up his story into the invisible world, passes out of the range of criticism!" Turn we again to Latham, and he tells us the Pelasgi were " perhaps slavonic ;" while Clavier, Larcher, Niebuhr, Müller, and Raoul Rochette, may all be studied for conflicting theories on the meaning of the term here employed as a definite or definable one. In the table where it occurs, it is adopted only for convenience, but it is difficult to imagine a less convenient term than one which is the very symbol of controversy and division of opinion. And as the seemingly precise name of Roman is liable to the utmost ambiguity in the hands of the Ethnographer, so is it in like manner with the significant ethnic term "Briton" here employed in its loose non-scientific sense, as applied to the mere occupants of the British Isles; as, on the same pages we find Dr. Thurnam quoted as using that of Anglo-Saxon to indicate the clearly defined Germanic race of Pagan colonists of Britain in the centuries immediately succeeding Roman occupation; while when Dr. Morton is referred to, it is found applied to multifarious colonists of the New World : the very first example betraying the unscientific application of the term to one rejoicing in the thoroughly cambro-celtic name of Gwillym ! In truth, when the American Ethnologist takes leisure to analyse the constituents of his own English-speaking fellow citizens; made up of Celtic: Irish, Scottish, and Welsh, fully as much at least as of Anglo-Saxon : Scot and Englishman ; not to mention Gallic, Iberian, Italian, Polish, Hungarian, old Dutch, and modern Germanic continental elements ;- still less the hybrid tinges of Red, or Black blood, which constitute the theme of one of the most interest-

ing chapters of this work,—he will take the edge off some of the finest Anglo-Saxon figures of speech of American oratory !

We believe the great majority of the students of this, the youngest of all the sciences, will heartily sympathise in the views which have guided Dr. Meigs of Philadelphia, in the treatment of the important department entrusted to him in the preparation of the volume under consideration. "I have confined myself," he remarks, " to a simple statement of facts, carefully and designedly abstaining from the expression of any opinion upon the prematurely, and perhaps in the present state of our knowledge, unwisely mooted questions of the origin and primitive affiliations of man. Not a little study and reflection, incline me to the belief that long years of severe and earnest research are yet necessary, before we can pronounce authoritatively upon those ultimate and perplexing problems of Ethnology." It is because we entirely concur in this opinion; and believe that the elimination of the necessary data on which Ethnological science must be built up, and the final recognition of the important truths which it is destined to establish, can only be retarded, by the diversion of its investigators into premature and bootless fields of polemics, that we have occupied so much space, with what we would otherwise have gladly left unsaid. What better can the Ethnologist hope for than that which has already been experienced by the Geologist; who has had to read in more recent octavos the recantation of his earlier quartos, and to confess on awaking, that, like Alnascar in the Arabian Tales, he had been expending the wealth of a dream in a triumph as baseless. It is facts alone we want at present; carefully, accurately, and unprejudicedly noted facts. These once accumulated, will fall into their order in due time, and the legitimate conclusions they point to, whatever they may be, will carry conviction to all honest seekers after truth, and find no lack of adherents "morally brave enough to avow them."

The "Indigenous Races of the Earth," is a work which embodies the results of much zealous industry and careful research. In one chapter, M. Maury discusses "The distribution and classification of Tongues ;" going over ground investigated by Sir Wm. Jones, Jacob Grimm, Humboldt, and later philologists : and placing the important results arrived at in a very concise and agreeable form. Next come the "Inconograhic researches on human Races and their Art," by Francis Pulszky : an interesting and comprehensive monogram, admitted by Dr. Nott and Mr. Gliddon into their new volume, with

honest candour, as a correction of previous speculations in a similar line of inquiry. The essay is replete with interest, copiously illustrated, and embodies the fruits of a varied familiarity with ancient works of art, which has been fully appreciated by those who have had the privilege of listening to the lectures delivered by him in England on cognate themes. Nevertheless, in his Ethnological deductions, we see once more how far we are yet from any certain terra firma. Who, for example, shall determine the ethnic character of the Etruscans, when he must decide between Niebuhr, Donaldson, Raoul Rochette, Pritchard, Latham, and Pulszky ? Here, however, is an accumulation of valuable materials, accompanied with highly suggestive hints as to the mode of using them, by the historical ethnographer, to whom such data will not be the less appreciated, even when he may claim the right to exercise his own judgement in determining their bearing on the general questions to which they are here applied, and the legitimate conclusions which flow from them.

Of Dr. Meigs' paper devoted to "The cranial characteristics of the Races of Men," it is sufficient to say that it is a valuable resumé of the labours of Morton, enlarged by many independent observations; with a cautious and discriminating effort to indicate the legitimate deductions which appear to its author to follow from the facts he has established.

Finally, it only remains for us to notice Dr. Nott's discussion of the important subject of "Acclimation; or the comparative influence of climate, endemic and epidemic diseases, on the races of men." Many of the questions discussed are of the highest interest. The nature and extent of acclimation for example, is curiously illustrated. So also, the effects of race, hybridity, various admixtures of blood, climate, &c., in reference to disease, as set forth from the results of observations extending over a course of twenty years professional experience, cannot but be studied with earnest attention, by all who have learned to appreciate the difficulties which gather around the great ethnological problem. The field of this author's observations, moreover, lies in that southern region of this continent where the meeting together of the white, red, and black races, under such peculiar circumstances, affords remarkable facilities for the accumulation of facts of the widest significance and value. Dr. Nott has his own special point of view, and he accordingly discusses those of Pritchard, and others who differ from him, with all the advantage of his practical experience, and command of authenticated personal observations. But besides his own data, he has accumulated much

curious information gathered from various independent sources, and from ancient and modern writers on the subject. Important statistical notes are compared and discussed in all their bearings, and partial deductions of former writers, are corrected by his own more enlarged experience. The conclusions he arrives at have already been set forth in the *Types of Mankind*, and need not now be discussed. The facts of such an observer are valuable contributions to science, independently of all deductions which to him may seem legitimately to flow from them. These are reiterated here in all their comprehensiveness, as conclusions drawn from "the long chain of facts" presented by himself and his collaborateurs in the production of the volume under review.

Such is a hasty glance at some of the varied contents of this new contribution to the science of Ethnology, from what may be specially designated as the American point of view. We have had to choose between a hasty notice of it immediately on its appearance, or a more careful study and discussion of its contents in a future number, when we must have followed in the wake of other reviewers, and referred to a book probably already in the readers hands. We have preferred the former alternative ; as our hasty notice may serve to direct the attention of some of our readers to it at an early date, and so afford them the opportunity of making for themselves such a careful and leisurely study of the varied contributions of its authors, as their merits deserve. We would only add, that the style in which the work has been produced, and the price at which it has been furnished to subscribers, amply justify the statement of the publishers, that monetary considerations have exercised little influence on the pains bestowed by the authors on their various contributions.

D. W.

## SCIENTIFIC AND LITERARY NOTES.

## GEOLOGY AND MINERALOGY.

### CALCAREOUS CONCRETIONS FROM BUCKINGHAM, ENGLAND.

Dr. G. D. Gibb, of Guildford Street. London, has kindly forwarded to the Canadian Institute, a large collection of the peculiar concretionary bodies lately figured and described in the *Illustrated London News*, under the term of "Fossi Marine Vegetable Remains." These bodies occur in large numbers in a deposit of "brick clay" at Tingewick, near Buckingham, and are supposed to have been

derived from the denudation of the chalk beds of the neighbouring cretaceous districts. They appear to have attracted more than ordinary attention, various notices of them having been published by Mr. Stowe of Buckingham, (to whom the Institute is indebted for the specimens forwarded through Dr. Gibb.) the Reverend S. G. Osborne, and others; but concretionary bodies of a more or less similar nature, are well known to be of common occurrence, and frequently to present imitative forms of a very varied character.\* As pointed out on their first ' discovery, by the Reverend Professor Sedgwick, the term "fossil vegetable remains," applied to these concretions, is altogether a misnomer; although the original perishable nuclei, around which the calcareous deposition took placesupposing a nucleus to have been present at all-may very possibly, though not necessarily, have been fuccidal. We quote the following passage from Dr. Gibb's communication, forwarded with the specimens in question :- "The presence of fossil infusoria seen in these specimens, does not necessarily prove them to be organic or marine, because we know very well that such bodies may have become incorporated or introduced from without, during the formation of the bed of clay from the debris of the chalk and other rocks. That such may be the case, I think there cannot be any doubt, and I am supported in this view by my friends Mr. J. W. Salter, Mr. T. Rupert Jones, and others. Mr Salter, moreover thinks such concretions are the commonest things in nature, and such as might be expected in argillaceous matters c ntaining carbonate of lime. They have assumed a flattened and compressed form, owing probably to pressure from the surface above. I am free to admit, however, that the material forming these concretions, may have become deposited around some marine vegetable remains, in consequence of the rather unusual forms assumed. In beds of clay employed for economic purposes, numerous concretions, lassuming various forms, mostly rounded, are very frequently found by the workmen, especially when the clay contains much calcareous matter. The workmen call them "race," and they consist of quartz-sand, mica more or less decomposed felspar, peroxide of iron, and a large proportion of calcareous particles.<sup>+</sup> The greater part, if not the whole of the latter, Mr. C. H. Sorby, believes to have been derived from the chalk; for numerous characteristic fragments of the Foraminifera, of which that deposit is almost entirely composed, are found in it. He thinks such concretions are formed from a mixture of chalk and fine clay, and that they have become consolidated by the action of carbonic water. Such, I conceive would be also an explanation of the specimens from Tingewick, with the possible exception of a form or shape constituting a nucleus."

#### COAL FIELDS OF KENTUCKY.

The following remarks on the coal deposits of Kentucky, are extracted from the

† Quarterly Geological Journal, vol. 8, p. 186.

<sup>\*</sup> We may mention here, that we have recently placed in the collection of the Canadian Institute, some peculiar, silicious concretions, (hitherto, we believe, unnoticed,) from the Black River Limestone of Lake St. John, near the Indian Village of Rama, north-east of Lake Simcoe, in Canada West. Some of these strikingly resemble bones of various kinds; and they present moreover, an internal cavity, often lined with a druse of minute quartz crystals. Their concretionary character is, however, quite evident. One of the specimens obtained, exhibits on its surface a strongly marked impression of the flat valve of an Orthis --probably O. testudinaria, or O. costalis. It may also be mentioned in connection with this subject, that the Palæotrochis of Emmons, a supposed fossil coral, has lately been shewn by Professor Hall, to be merely a concretionary structure. E. J. C.

recent Report on the Geology of that State, by Dr. Dale Owen: ' In south-western Kentucky, the whole of eight counties, and a part of four other counties, are embraced in the middle coal field of the Mississippi valley, or the coal field which lies partly in Illinois, partly in Indiana, and partly in Kentucky. In eastern Kentucky, fifteen counties, and a large area of five more counties, are included in the great Appalachian coal field, i e. in the coal region occupying the western slopes of the Alleghany Mountains, and the Cumberland range, situated partly in Pennsylvania, Virginia, Ohio, Tennesee, and those above mentioned eastern counties of Kentucky." . . . . After describing the boundaries of the south-western coal field, the author continues as follows: "The coal beds included in these counties, (Christian county, Baker county, &c.,) naturally divide themselves into Upper and Lower coal measures. These are separated from each other, not only by a prominent sandstone formation, (the so-called Anvil Rock,) but they have been cast off from continuity, immediately on the Obio River, by an extensive uplift and dislocation of the geological formation which stretches from Gold Hill, on the Illinois side of the Ohio River, across the bed of that stream at Shawneeton, to Bald Hill, in Union County. The Topographical Assistant, (S. S. Lyon,) in his detailed survey of Union County, has traced a continuation of this upheaval in a nearly east and west course through the entire county. Beyond the Valley of Cypress, this disturbed belt has an increased width to the boundary of Henderson County. Beyond this point it has not yet been systematically followed; but the occurrence of disturbances, with a reversal of dip, near the confluence of Pond and Green Rivers, render it probable that it can be traced completely through the coal field. In Kentucky there is no evidence, whatever, that this disturbance occurred prior to the deposition of the coal measures; on the contrary, it has implicated in its movements, not only the sub-carboniferous limestone, and millstone-grit, but also the entire coal formation which lies in conformable dip on either side of the axis." Almost all of the coal beds are stated to occur in connexion with under clavs containing stigmaria. At. least eight workable seams occur in the Upper measures and ten in the Lower, varying in thickness, from about a foot to seven feet. Beds of clay iron ore are likewise abundant.

### ZIRCON WITH BASAL PLANES.

The absence of the basal form, is one of the most salient characteristics of zircon crystals. M. Friedel, however, has recently announced\* the existence of two small crystals in the collection belonging to the Ecole des Mines, in which this form occurs. These crystals are said to have been brought from Serrode-Frio in Brazil. They have not been analysed, but their identity with zircon seems to be established by their physical and blow-pipe characters, and by the general correspondence of their angles with the measurements of that mineral. Besides the basal plane, the following forms, were also recognized, viz:—the first or diaxial vertical prism, (placed, however, as a monaxial prism in M. Friedel's figures, in conformity with the system of the French school); the triaxial pyramids or octahedrons P,  $\frac{1}{2}$  P (not previously recognized), and 3 P; and the eight-sided pyramid 3P3. The new form denoted by the symbol  $\frac{1}{2}$  P, comes out nearest to that notation, but the agreement is by no means close. According to M. Friedel's measurements, P: P (in the crystal in which the new form occurs.)  $= 125^{\circ} 5'$ ; making the vertical axis, 0,6082; whilst in the form in question, the same angle is stated to be 149° 30' which would give 0,2334 for the vertical axis.

#### CALC-SPAR CRYSTALS FROM SOUTH AFRICA.

The cleavage rhombohedron of Calcareous Spar, in *simple crystals*, is well known to be exceedingly rare. As truly stated by M. Dufrenoy, the simple rhombohedrons often labelled "calc-spar" in collections, belong, in general to Dolomite. The writer of these notes, however, has lately received with other minerals from Namaqualand, in South Africa, several large crystals of calcareous spar, occurring in the simple cleavage form. Most of these crystals are somewhat distorted by elongation, and all are striated on the surface in the direction of a plane at right angles to the vertical axis. They are associated with trap, or trap tufa.

In the dolomite rhombohedrons, the obtuse angle over a polar edge, equals 106° 15'; and the presence of magnesia may be readily detected by dissolving the substance in a few drops of diluted hydrochloric acid—adding a drop of nitric acid, and boiling (to convert any Fe O that may be present, into Fe<sup>2</sup>O<sup>3</sup>)—and precipitating by ammonia and oxalic acid the iron (if present) and the lime. The magnesia can then be thrown down from the filtered solution, by phosphate of soda, and tested with nitrate of cobalt before the blowpipe. If conducted in test-tubes, and on small quantities, the whole process need not occupy more that ten minutes.

The following logarithmic formula (extracted from some notes by the writer, in the Phil. Mag. of August, 1853,) for the determination of the vertical axis in rhombohedrons, may not be unacceptable to some of our readers :--

Let a = half the inclination, as obtained by measurement, over a polar edge; b, the inclination of a rhombohedral face on the vertical axis; and v, the axial length required. Then:

> Log cos  $b = \log \cos a + 0.0624694$ ; Log  $v = \log \cot b - 10.0624694$ .

### PHYSIOLOGY AND NATURAL HISTORY.

#### CANADIAN STRIGIDAE.

In communicating the following notes on the Canadian Strigidae, the object is mainly to procure information. Nevertheless, those who have not studied the subject may be interested in learning how many varieties of these curious and remarkable birds frequent the neighbourhood of Toronto; as well as in knowing that a tolerably complete collection of specimens of them have been admirably preserved for the University Museum, by the late Mr. Hadgraft and Mr. Passmore, and cannot but prove attractive to every lover of natural objects. It is not, perhaps, presuming too much to hope that intelligent and scientific gentlemen of this district, on observing what has been already procured will use their endeavours to extend the list and assist in obtaining the few other species still wanting, among the more familiar examples, or any novel or rare forms which may present themselves. The nocturnal Raptorial birds forming the family of STRIGIDAE or owls, are divided by Mr. Gray into four sub-families.

The SURNINAE, or Hawk owls, have the head small in proportion, without tufts, and with the facial disc imperfect above the eyes.

The University Museum possesses Surnia Ulula, the hawk owl, a moderate sized species abounding in the fur-countries, and occasionally seen in our district.

Nyctea Nivea, the Snowy owl, a well known and very handsome bird; and one example out of several, we might perhaps hope to obtain, of the genus Athene passerinoides, one of the birds popularly confounded under the name of the little owl.

The sub-family BUBONINAE, have the head broad and somewhat flat, with usually two prominent tufts; the facial disc being imperfect above the eyes.

The most conspicious example is *Bubo Virginianus*, the great Virginian horned owl, one of the larger sized, of very beautiful and characteristic form. Besides this, we have two species of *Ephialtes*, small owls of interesting character:

*Ephialtes Asio*, the American Seops eared owl, or little screech owl, and *Ephialtes Nudipes*; the naked footed owl, which latter may probably belong to a different genus.

The sub-family of the SYRNINAE, (the name of which comes too near in sound to the first.) has the facial disc complete above, the tuft often absent, and when present, of fewer feathers. It affords us two fine species of Syrnium:

Syrnium cincreum, the great cincreous owl, a magnificient bird inhabiting deep woods, abounding in the fur countries, and occasionally visiting this more southern district, of which the University has recently obtained a pair from Mr. Passmore; and,

Syrnium nebulosum, the barred owl, one of the commonest species in our neighbourhood.

There are also in the collection two species of Otus:

Otus Wilsoni, the American long eared owl, which has generally been confounded with Otus vulgaris, the European long eared owl, but is abundantly distinct, and,

Otus Brachyotus, the short-eared owl, common to both continents.

The remaining sub-family, consists of the STRIGINAE, Barn owls, a race entirely without tufts, with the facial discs complete, generally of a somewhat triangular figure.

Not to leave the group without illustration, a European specimen of Strix Flammea, the common barn owl, or white owl, stands with the others. This species is said to belong to America, as well as Europe, but Audubon, gives reasons for supposing the American form to be distinct, and judging from his fine figure compared with the European bird, there is no doubt that he is right. The American specimens have hitherto been found exclusively in the south, whereas the European bird might rather be expected to inhabit more uorthern regions. Eleven species of owls now in the University Museum, have been procured around Toronto in a short period, and it may be reasonably hoped that further additions will be contributed to the collection from the same neighbourhood, as well as from other parts of the Province.

The University collection contains in almost every instance, a pair of each species, displaying well the sexual differences in size and plumage.

### ETHNOLOGY AND ARCHÆOLOGY.

### ETHNOLOGY AND ARCHÆOLOGY.

## ORANIA OF THE ANCIENT ROMANS.

Among the abstracts of papers in the departments of Ethnology, printed in the Report of the British Association for 1855, is one by Joseph Barnard Davis, M.R.C.S; F.S.A., on the forms of the Crania of the Ancient Romans, which possesses an interest on various grounds. There is indeed an important element of error, probably not overlooked by the discriminating observer, though unnoticed in the following abstract. It would be contrary to all known facts to assume that Crania found in Roman Cemeteries at the British sites named below, were necessarily those of Romans. In the majority of cases, our information would justify an opposite conclusion. The Roman Legions, were Roman only, politically, not ethnologically. At Eburacum for example, the permanent station of the Sixth Legion, the memorial inscription of Lucius Duccius, proves that he was a native of Gaul; while the inscriptions on tiles found there, pertain both to the sixth, and to the ninth, a Spanish legion. Inscriptions on altars and sepulchral slabs: the Notitia ; the earlier notices by Tacitus of the Roman forces in Britain &c., all combine to prove that of the ethnological elements introduced into Britain by Roman occupation, we must include Gauls, Germans, Iberians, Greeks of Asia Minor, and even Africans; and indeed so small was the actual Italian element of population, that it would be difficult to over state the chances of an Anglo-Roman Sepulchre containing a representative of any of the conquered provinces of the empire, rather than by an actual Roman. In the special case however, described, and chiefly dwelt upon here, it will be seen that means of identification existed. and receive due consideration. The following is the abstract of Mr. Davis's paper, containing ampler details on a subject previously noticed in the Canadian Journal, (vol. I, p. 76.)

"A numerous series of ancient Roman skulls, derived from three different sources in Italy and from the Roman cemetevies at Eburacum, Londinium, Lindum, and Glevum, has fallen into the hands of the author. As the basis of these observations, he selects the cranium of THEODOBIANUS, a Roman of consequence, who died at Eburacum in his 35th year, and whose inscribed stone sarcophagus was discovered many years ago. The venerable antiquary of Roman York, the Rev. Charles Wellbeloved, has referred him to a Roman family of Nomentum. a town of the Sabini in Italy. His skull is an elegant example of the capacious Roman cranium. It is marked by the squareness of face common to the typical form of the Roman head, the fine prominent nasal bones of aquiline profile, their position being more expressed from the broad nasal processes of the superior maxillæ-the expanded and capacious forehead, of somewhat low elevation. terminating below in a prominence of the supra-nasal region, which distinguishes it from the regular skull of Grecian type. It may be regarded as belonging to the typical section of ancient Roman crania, although not presenting the typical character in so decided a form as others exhibited. It will come under the division of what may be called platy-cephalic crania, those distinguished by a horizontal expansion of the vertical region. The diacritical marks which distinguish the crania of the ancient Britons from those of the ancient Romans may be expressed as follows: after remarking that those of the Romans were decidedly the larger, he adds :-- The face of the former was rather shorter, more

### CANADIAN INSTITUTE.

regular, deeply marked by muscular impressions, with a frowning supra-nasal and supra orbital prominence; short but abruptly eminent nasal bones, rising suddenly out of the depression at the root of the nose; the forehead narrower, yet rising at about the same angle to nearly an equal elevation. The face of the ancient Roman was slightly longer, fully as wide in all parts, and sensibly wider in the frontal region, and as the angles and condyles of the lower jaw. This inereased breath at the two extremities, with want of elevation of forehead, imparted to the countenance that quadrangular appearance so commonly observed in the statues of ancient Romans of Consular and Imperial times. The calvarium in the typical British skull is marked by particular shortness; that of the ancient Roman viewed vertically is not remarkable for shortness, whilst it preserves a considerable breadth. It is fully half an inch longer than the British, and yet aomewhat wider. Commencing in the frontal region, this width extends to the temporal in all its parts, and to the parietal. It is on this feature we are disposed to rest its peculiarity, and to call it pealty-cephalic, to express that especially expanded form belonging to it without marked loftiness. Probably ancient British and Roman skulls agree pretty closely in elevation. The well-known peculiarity in the nasal bones of the latter, mostly conjoined with remarkable breadth and elevation of the nasal process of the superior maxillary, is another typical mark.

The author next refers to two selected from several skulls obtained from burials on the Via Appia—to a series derived from the Roman cemetery without the south-western gate of Eburacum in 1852—to others obtained from the Roman Cemetery of Londinium in the Borough, dug up from the 'Roman level' about 16 feet below the present surface. He compares the physical characters of the ancient Romans with those which may still be observed in the modern population of Italy, and infers that 'notwithstanding the vicissitudes of all the ages intervening between the present and imperial times, we have just ground for believing that the indicia of the ancient Roman people are still unextinguished in their descendants.' He concludes by suggesting the inquiry into the degree in which these peculiarities of the Romans may be traced in the people of Britain."

Since this notice of the general subject of Roman Crania, and of the special example from Roman York was read before the British Association, the York Cranium has been figured in the beautiful and valuable work, the "Crania Britannica," now publishing under the joint editorship of Mr. Davis and Dr. Thurnam. We shall have an opportunity of noticing its earlier fasiculi in a future number.

D. W.

## CANADIAN INSTITUTE.

FIFTH ORDINARY MEETING. -24th January, 1857.

The Hon. the Chief Justice DRAPER, C. B., President, in the Chair.

The following Gentlemen were elected Members ;

GEORGE S. MCKAY, ESQ., Toronto. JAMES H. MORRIS, ESQ., Toronto. Dr. B. H. STAMERS, Toronto.

Dr. WALTER GEIELE, Toronto.
### CANADIAN INSTITUTE.

The following donations were announced, and the thanks of the Institute voted to the Donors :

- 1. By Henry G. Bohn, Esq., London, England, per A. H. Armour, Esq., ; "Forster's Critical Essays." Vol. 1.
  - "Guizot's History of Civilisation," in three volumes.
  - "Thierry's Norman Conquest," in two volumes.
  - " Michael Angelo and Raphael."
  - "Walton's Complete Angler," by Jesse, Plates.
  - " Masterman Ready, or the Wreck of the Pacific," by Capt. Marryat.
  - "Blair's Chronological Tables, enlarged and continued." Double volume.
  - "Memoirs of the Duke of Sully, Prime Minister to Henry the Great," in four volumes.
  - " Pliny's Natural History." Vol. 5.
  - "Quintlian's Institutes of Oratory." Vol. 2.
  - " Demosthenes against Midias," &c. (Kennedy.)
  - "Dictionary of Classical Quotations."
  - "The Crystal Palace Company."
  - " Life of George Washington," by Washington Irving. Vol. 3.
- 2. By Hon. J. M. Brodhead, Washington, per A. H. Armour, Esq., :

"Regulations for United States Consular officers."

- "Report on the Finances (United States), 1855-6."
- "Commerce and Navigation of the United States for year ending 30th June, 1856."
- 2. From His Excellency the Governor General, per R. T. Pennefather, Esq. :
  - "Address on the opening of the One Hundred and third Session of the Royal Society of Arts, London; delivered by Col. Sykes, F.R.S., Chairman of the Council, Nov. 19th, 1856." Pamphlet.
  - " Parliamentary List of Council and Officers, and Committees of Reference. Two pamphlets.
- 4. By Professor H. Y. Hind, M. A. :
  - <sup>4</sup> A collection of Geological Specimens, consisting of: Trilobite Beds: Utica Slate, Blue Mountains, Collingwood. Graptolite: Red River, Humber, Hudson River Group.
    Fucoid, from the Hudson River Group, Humber River.
    Ripple Mark, \_\_\_\_\_\_\_ do.
- Black River and Bird's eye Limestone, from Lake Couchiching Tracks of Crustacea, Potsdam Sandstone, Beauharnois."

The following papers were then read :

1. By Professor KINGSTON, M.A., :

"On the practical application of the Electric Telegraph, for predicting storms." On the motion of Colonel Baron de Rottenburg, it was ordered that Professor Kingston's paper be referred to a committee, with a view to bring the matter under the notice of the Government, and that the committee consist of Professors Kingston, Croft, and Cherriman, and the mover.

- 1. By Professor CHAPMAN :
  - "On some Crystals of Carbonate of Lime, from South Africa."

## CANADIAN INSTITUTE.

SIXTH ORDINARY MEETING, -31st January, 1857.

The Hon. the Chief Justice DRAPER, C. B., President, in the Chair.

WILLIAM BENNET RICH, Esq., Goderich, was elected a Member.

The following Donations were announced and the thanks of the Institute voted to the

Donors :

1. By the Trustees of the New York State Library :

"Copy of a new Catalogue, and several Pamphlets."

2. By Major F. Wells, Royal Regiment:

A Stone Hammer, picked up in one of the Trenches of Sebastopol, third parallel left attack, about three feet six inches under ground.

Major Wells, by whom this interesting relic was secured while actively engaged in the Siege of Sebastopol, being present, the President conveyed to him the thanks of the Institute for this donation, as a relic of the past, rendered doubly valuable from its constituting also a memorial of the memorable war in the Orimea.

 $The following \ paper \ was \ then \ read:$ 

By Professor Wilson, LL.D. :

"On the antiquity of the use of Narcotics in the Old and New World."

SEVENTH ORDINARY MEETING .- 7th February, 1857.

Colonel BARON DE ROTTENBURG, Vice-President, in the Chair.

The following Gentlemen were elected Members:

Mr. Sheriff TREADWELL, L'Original, C. W.,

ROBERT HEDDLE, Esq., Toronto.

WILLIAM COBB, Esq., Solicitor, Toronto.

RICHARD GRAHAME, Toronto, (Junior Member.)

The following papers were then read:

1. By Professor D. WILSON, LL.D.:

"On the Customs, Usages, and Superstitions of the Old and New World, in relation to Tobacco and other Narcotics."

In illustration of this paper, Mr. Paul Kane exhibited a curious collection of Pipes, and other specimens of American native art, executed and used by the various Indian Tribes of the North West.

2. By Rev. Professor HINCKS, F.L.S., :

" Notes on the Strigidae found in the neighbourhood of Toronto."

Specimens were exhibited from the collection belonging to Toronto University

EIGHTH ORDINARY MEETING .- 14th February, 1857.

Professor E. J. CHAPMAN, Vice-President, in the Chair.

The following Donations to the Library were announced, and the thanks of the Institute voted to the Donors :

From A. H. Armour, Esq:

"Outlines of the Geology of Ohio, by C. W. Whittlesay, with a map. From the Author:

"Natural History of Vermont, a Lecture by Z. Thompson."

" "Preliminary Report on the Geology of Vermont."

The following papers were then read:

1. By JOHN LANGTON, Esq., M. A., :

"On the early French discoveries in North America."

Mr. Langton illustrated his paper with a series of tracings of early French maps, which he presented to the Institute.

Ordered, that the thanks of the Institute be presented to Mr. Langton, for his valuable donation.

2. By Professor CHAPMAN :

"Remarks on the classification and leading characteristics of Palæozoic Corals," illustrated by means of explanatory drawings.

NINTH ORDINARY MEETING.-21st February, 1857.

Prof. E. J. CHAPMAN, Vice-President, in the Chair.

The following Donation for the Library was announced, and the thanks of the Institute voted to the Donor;

From the Hon. J. M. Brodhead, Washington :

"Statistical Report on the Sickness and Mortality in the Army of the United States, from January 1839, to January 1855." I vol.

The following Gentleman was elected a Member;

W. R. Abbot, Esq., Toronto.

The following pupers were then read:

1. By P. FREELAND, Esq., :

"On a new construction of the stage of the Microscope."

2. By Prof. KINGSTON, M.A., :

"Report on the Meteorological Observations made during the year 1856."

TENTH ORDINARY MEETING .- 28th February, 1857.

Prof. E. J. CHAPMAN, Vice-President, in the Chair.

The following Donations for the Library were announced, and the thanks of the Institute voted to the Donors:

1. From the Hon. J. M. Brodhead, Washington, per A. H. Armour, Esq., Toronto : "Commercial relations of the United States, with all other Nations." Part I., vol. I. "United States Naval Astronomical Expedition." Vol. VI.

"Proceedings of the Commission for the Settlement of Claims between the

United States and Great Britain."

2. From Ecole des Mines, Paris:

" Annales des Mines, Tome VIII., IX.

On the motion of F. W. Cumberland, Esq., seconded by Rev. W. S. Darling, Dr. S. Stratford, of New Zealand, was proposed as a Corresponding Member.

The following paper was then read by Prof. Croft:

"Notes on the Natural History of New Zealand, by S. Stratford, M.D." A Donation of illustrative specimens was laid on the table, from Dr. Stratford.

Ordered, that the cordial thanks of the Institute be presented to Dr. Stratford, for his valuable donations, and for the accompanying information in regard to New Zealand.

Colonel Baron de Rottenburg gave notice that the Report of the Committee, to whom was referred the communication of Lieut. Ashe, Royal Navy, relative to the extension of the Astronomical Observatory at Quebec, would be taken up at the next meeting.

# No. X.-JULY, 1857.

# NARCOTIC USAGES AND SUPERSTITIONS OF THE OLD AND NEW WORLD.

BY DANIEL WILSON, LL.D.,

PROFESSOR OF HISTORY AND ENGLISH LITERATURE, UNIVERSITY COLLEGE, TORONTO.

Read before the Canadian Institute, 31st January, 1857.

In attempting to determine the elements on which to base a system of classification of the diverse types or varieties of man, there are frequently one or two prominent characteristics which, alike among ancient and modern races, appear to supply at least convenient tests of classification, while some are deserving of special consideration as indicators of more comprehensive and far-reaching principles. The ancient epithet "barbarian," had its origin in the recognition of this idea; and we still apply that of "woad-died" to the old Briton as the fittest which our knowledge of him supplies. With the Jew and his semitic congeners, the rite of circumcision is a peculiarly distinctive element of isolation, though carried by Islamism, with the Arabic tongue, far beyond their ethnic pale. Brahminism, Buddhism, Parseeism, Sabaism, Fetisism, and even Thuggism, each suffice to supply some elements of classification. The cannibal New Zealander, the large footed Patagonian, the big lipped Babeen, the flat-headed Chinook, the woolly-haired Negro, the clucking Hottentot, and the boomerang-armed Australian, has each his special feature, or peculiar symbol, more or less fitly assigned to him : and not less, but more distinctly characteristic than any of these

VOL. II.-Q

are the scalp war-trophy, and the peace-pipe of the American Indian, —the characteristics not of a tribe, or a nation, but of a whole continent. Of the indigenous uniqueness of the former of these there is no question. It may not be altogether unprofitable to reconsider the purely American origin of the usages connected with the latter, on which doubts have been repeatedly cast, and more especially by recent writers, when considering the inquiry from very diverse points of view.

Among the native products of the American continent, there is none which so strikingly distinguishes it as the tobacco plant, and the purposes to which its leaf is applied; for even were it proved that the use of it as a narcotic, and the practise of smoking its burning leaf, had originated independently in the old world, the sacred institution of the peace-pipe must still remain as the peculiar characteristic of the Red Indian of America. Professor Johnston, in his " Chemistry of Common Life," remarks with reference to this and others of the narcotics peculiar to the new world :-- " The Aborigines of Central America rolled up the tobacco leaf, and dreamed away their lives in smoky reveries, ages before Columbus was born, or the colonists of Sir Walter Raleigh brought it within the precincts of the Elizabethean Court. The cocoa leaf, now the comfort and strength of the Peruvian muletero, was chewed as he does it, in far remote times, and among the same mountains, by the Indian natives whose blood he inherits." The former of these narcotics, however, it is scarcely necessary to say, was not confined, within any period known to us, to central America, though its name of tobacco. -derived by some from the Haîtian tambaku, and by others from Talaco, a province of Yucatan, where the Spaniards are affirmed to have first met with it,-appears to have been the native term for the pipe, and not for the plant, which was called kohiba.

So far as we can now infer from the evidence furnished by native arts and relics connected with the use of the tobacco plant, it seems to have been as familiar to most of the ancient tribes of the north west, and the Aborigines of our Canadian forests, as to those of the American tropics, of which the *Nicotiana Tabacum* is believed to be a native. No such remarkable depositories indeed have been found to the north of the great chain of lakes, as those disclosed to the explorers of the tumuli of "Mound City," in the Scioto valley, Ohio, from a single one of which, nearly two hundred pipes were taken; most of them composed of a hard red porphyritic stone, with their bowls elaborately carved in miniature figures of animals, birds,

reptiles, &c., executed with great skill and fidelity to nature.\* But though not found in such numbers, sufficient examples of this class of relics occur within the Canadian frontier to show the contemporaneous practice of the same arts and customs in this northern region, or to prove such an intercourse with the pipe-sculptors of more southern latitudes, as is assumed in the case of the "Mound Builders," by writers to whom any remote and undefined source ever seems more probable than the one under consideration. Among various examples of such Canadian relics in my own possession are two stone pipe-heads found on the shores of Lake Simcoe. One of these, formed of a dark steatite, though imperfect, exhibits in its carving-a lizard climbing up the bowl of the pipe, with the underside of its lower-jaw ingeniously cut into a human countenance peering over the pipe bowl at the face of the smoker-the same curious imitative art of the native sculptor, as those engraved by Messrs. Squire and Davis, from the ancient mounds of the Mississippi valley. The other is decorated with a human head, marked by broad cheek-bones, and large cars, and wearing a flat and slightly projecting head dress. The material in which the latter is carved is worthy of notice, as suggestive of its pertaining to the locality where it was found. It is a highly silicious limestone, such as abounds on the shores of the neighbouring Lake Couchiching, and which from its great hardness was little likely to be chosen by the pipe sculptor as the material on which to exercise his artistic skill, unless in such a locality as this, where his choice lay between the hard, but close grained limestone, and the still more intractable crystalline rocks of the same region. Canadian examples of pipesculpture, in a great variety of forms, executed in the favorite and easily wrought red pipe-stone of the Coteau des Prairies, also occur ; but these are generally supposed to belong to a more recent period, and differ essentially in their style of art from the pipes of the mound builders, worked in granite, porphyry, and limestone, as well as in the steatites, and other varieties of the more easily wrought stones which admit, like the red pipe stone, of the elaborate carving and high degree of finish most frequently aimed at by them. In addition to those, another class of pipes, of ruder workmanship in clay, and ornamented for the most part, only with incised chevron and other conventional patterns, exhibiting no traces of imitative art, are of frequent occurrence within the Canadian frontiers; and to these I propose to refer more minutely before closing this paper, as objects

<sup>\*</sup> Smithsonian Contributions to Knowledge. Vol. I. p. 152,

possessing some value in relation to the history of the singular native custom for which such implements were constructed, and to its early practice in Europe. Meanwhile it may be noted that the terms existing in the widely diversified native vocabularies are irreconcileable with the idea of the introduction of tobacco among the northern tribes of the American continent as a recently borrowed novelty. We learn from the narative of Father Francisco Creuxio, that the Jesuit missionaries of the 17th century, found tobacco in abundant use among the Indians of Canada. So early as 1629 he describes the Hurons as smoking immoderately the dried leaves and stalks of the nicotian plant commonly called tobacco or petune; and such was their addiction to the practice that one of their tribes in Upper Canada, received the designation of the Petunians, or smokers. from the latter name for the favourite weed.\* This term appears to be of Floridian origin, and was perhaps introduced by the missionaries themselves from the southern vocabulary. But the the Chippeway name for tobacco is asamah, seemingly, as Dr. O'Meara-now, and for many years resident missionary among the Indians of the Manitouanin Islands,-assures me, a native radical having no other significance or application. So also the Chippeways have the word butta to express smoke, as the smoke of a fire; but for tobacco fumes they employ a distinct term : bucwanay, literally : " it smokes," the puckwana of Longfellow's "Hiawatha." Pwahqun is a "tobacco pipe;" and with the peculiar power of compound words and inflection, so remarkable in the languages of tribes so rude as those of the American forests, we have from this root : nipwahguneka : "I make pipes," kipwahguneka: "thou makest pipes," pwahgunea: "he makes pipes, &c.," so also, nisuggaswa : "1 smoke a pipe," kisuggaswa : "thou smokest," suggaswa : "he smokes." While therefore, Europe has borrowed the name of the Indian weed from that nortion of the new world first visited by its Genoese discoverer, the language of the great Algonquin nation exhibits an ancient and entirely independent northern vocabulary associated with the use of tobacco, betraying none of the traces of compounded descriptive terms so discernible in all those applied to objects of European

origin. The practice of smoking narcotics, is interwoven with all their habits, so that they even reckon time by pipes, using such word sentences as *ningopwahgun*, "I was one pipe [of time] about it".

In the Old World most of the ideas connected with the tobacco pipe are homely and prosaic enough: and though we associate the chibouk with the poetical reveries of the oriental day-dreamer, and the hookah with the pleasant fancies of the Anglo-Indian reposing in the shade of his bungaloose : nevertheless, the tobacco pipe constitutes the peculiar and most characteristic symbol of America, intimately interwoven with the rites and superstitions, and with the relics of ancient customs and historical traditions of the Aborigines of this New World. If Europe borrowed from it the first knowledge of its prized narcotic, the gift was received unaccompanied by any of the sacred or peculiar virtues which the Red Indian still attaches to it as the symbol of hospitality and amicable intercourse ; and Longfellow, accordingly, with no less poetic vigor, than fitness, opens his "Song of Hiawatha" with the institution of "the peacepipe," by the Great Spirit, the master of life. With all the unpoetical associations which are inseparable from the modern uses of the nicotian weed, it required the inspiration of true poetry to redeem it from its base ideal. But this the American poet has accomplished fully, and with the boldest figures. The Master of Life descends on the mountains of the Prairie, breaks a fragment from the red stone of the quarry, and fashioning it with curious art into a figured pipe-head, he fills it with the bark of the red willow, chafes the forest into flame with the tempest of his breath, and kindling it :

> Erect upon the mountains Gitche Manito, the mighty, Smoked the calumet, the peace-pipe, As a signal to the nations. And the smoke rose slowly, slowly, Through the tranquil air of morning, First a single line of darkness, Then a denser, bluer vapor, Then a snow-white cloud unfolding, Like the tree tops of the forest, Ever rising, rising, Till it touched the top of heaven, Till it broke against the heaven And rolled onward all around it.

And the tribes of the ancient Aborigines gathering from river, lake, and prairie, assemble at the divine summons, listen to the warnings and promises with which the Great Spirit seeks to guide them; and this done, and the warriors having buried their war clubs, they smoke their first peace-pipe, and depart :

While the Master of Life, ascending, Through the opening of cloud-curtains, Through the doorways of the heaven, Vanished from before their faces, In the smoke that rolled around him, The pukwana of the peace pipe!

It is no mean triumph of the poet thus to redeem from associations, not only prosaic, but even offensive, a custom which so peculiarily pertains to the usages and the rites of this continent from the remotest times of which its historic memorials furnish any trace; and which was no sooner practically introduced to the knowledge of the old world, than that royal pedant, king James, directed against it his world-famous "Counterblast to Tobacco," describing its use as "a custom loathesome to the eye, hateful to the nose, harmful to the brain, dangerous to the lungs, and in the black stinking fume thereof, nearest resembling the horrible stygian smoke of the pit that is bottomless !"

The history of the custom thus dignified by the assaults of royalty, and against certain uses of which the supreme pontiff, Urban. VIII., fulminated the thunders of the church, has attracted considerable attention in modern times on various grounds. In their relations to physiology the use and effects of narcotics claim an important consideration; and the almost universal diffusion of tobacco in modern times, accompanied with its peculiar mode of enjoyment, so generally adopted by the most diverse tribes and nations in every quarter of the globe, give its history a preeminence in any such inquiry. The questions as to whether the practice of smoking narcotics, or even the use and peculiar properties of tobacco, were known to the old world prior to the discovery of America, have accordingly repeatedly excited discussion; though it has not been always remembered that the inquiry as to the indigenous character of certain varieties of the tobacco plant in the old world, and even as to the use of such a narcotic, involve questions quite distinct from that of the origin of the very peculiar mode of partaking of the exhilerating or intoxicating effects of various narcotics by inhaling their burning fumes through a pipe.

The green tobacco, *nicotiana rustica*, cultivated in Thibet, western China, northern India, and Syria, is a different species from the American plant; and while it is affirmed by some to have been

brought from America, and even the precise date of 1570, is assigned for its importation into Britain, high authorities in Botany are still found to maintain the indigenous character of the nicotiana rustica, in some parts of the old world, as in northern India, where it is stated to grow wild. DuWalde, (1793.) speaks of tobacco as one of the natural productions of Formosa whence it was largely imported by the Chinese; and Savary, O'earius, Chardin, and other writers, are all quoted\* to show that the nicotiana Persica, which furnishes the famous shiraz tobacco, is not only indigenous to Persia, (an opinion favoured by high authorities in botany.) but that it was used for smoking from very early times. That all the varieties of the Nicotiana are not confined to the new world is unquestionable. Of. some fifty-eight admitted species, the great majority are indeed American, but a few belong to the newer world of Australia, besides those believed to be indigenous to Asia. It is not surprising therefore, that after all the attention which this subject has latterly, on various accounts, attracted, writers should be found to maintain the opinion that the use of tobacco as a narcotic was known and practised by the Asiatics, prior to the discovery of America. The oriental use of tobacco may indeed be carried back to an era old enough to satisfy the keenest stickler for the antiquity of the practice, if he is not too nice as to his authorities. Dr. Yates in his Travels in Egypt, describes a painting which he saw on one of the tombs at Thebes, containing the representation of a smoking party. But this is modern compared with a record said to exist in the works of the early fathers, and, at any rate, preserved as an old tradition of the Greek Church, which ascribes the inebriation of the patriarch Noah to the temptation of the Devil by means of tobacco; so that King James was not, after al!, without authority for the black stygian parentage he assigns to its fumes! Professor Johnston-who marshalls various authorities on the Asiatic use of tobacco for smoking, prior to the discovery of America, without venturing on any very definite opinion of his own, - quotes Pallas as arguing in favour of the antiquity of the practice from its extensive prevalence in Asia, and especially in China. "Amongst the Chinese," says this writer, "and among the Mongol tribes who had the most intercourse with them, the custom of smoking is so general, so frequent, and has become so indispensable a luxury; the tobacco-purse affixed to their belt so necessary an article of dress; the form of the pipes, from which the Dutch seem to have taken the model of theirs, so original;

<sup>\*</sup> A. C. M. Exeter. Notes and Queries. Vol. II. p. 154.

and lastly, the preparation of the yellow leaves, which are merely rubbed to pieces, and then put into the pipe, so peculiar, that they could not possibly derive all this from America by way of Europe, especially as India, where the practice is not so general, intervenes between Persia and China." But the opinions of Dr. Meyen, formerly Professor of Botany in the University of Berlin, are worthy of still greater weight, set forth as they are, alike on Archælogical and Botanical grounds. In his " Grundriss der Pflanzengeogruphie." or "Outlines of the Geography of Plants," recently translated for the Ray Society, he observes: "It has long been the opinion, that the use of tobacco, as well as its culture, was peculiar to the people of America, but this is now proved to be incorrect by our present more exact acquaintance with China and India The consumption of tobacco in the Chinese empire is of immense extent, and the practice seems to be of great antiquity, for on very old sculptures I have observed the very same tobacco pipes which are still used. Besides we now know the plant which furnishes the Chinese tobacco, it is even said to grow wild in the East Indies. It is certain that this tobacco plant of eastern Asia is quite different from the American species. The genus Nicotiana, generally speaking, belongs to the warmer zones, yet a few species of it have a very extensive area, and a great power of resisting the influence of climate, for they can be grown under the equator, and in the temperate zone, even far above 55° north latitude, where the mean summer heat is equal to 15.87° Cels. The southern polar limit for the culture of tobacco is not exactly known, but it seems to extend to the 40th degree of latitude, for in south America tobacco is cultivated at Conception, and in New Zealand enough is grown for the consumption there."\*

To India, then, Dr. Meyen inclines. with others, to refer the native habitat of an Asiatic tobacco, which he thus affirms to have been in use by the Chinese as a narcotic, and consumed by inhaling its smoke through a pipe, altogether independent of the introduction of this luxury to Europe by the discoverers of America in the fifteenth century. While the Turk still chews the opium in which he so freely indulges, the Chinese, and also the Malays smoke it, most frequently using as a pipe a bamboo, which serves also for a walking stick, and requires a very slight operation to convert it into an opium pipe. The Chinese opium smoker secures the utmost effects of that powerful narcotic by swallowing the smoke; and notwithstanding this mode of using the narcotic derived from the poppy is

<sup>\*</sup> Meyen's Outlines of the Geography of Plants. Ray Society. Page 361.

# OF THE OLD AND NEW WORLD.

acknowledged to be of comparatively recent introduction, when we call to remembrance that that strange people preceeded Europe in wood engraving, printing, the compass, and others of the most important of modern discoveries, there would be no just cause of surprise should it be proved that to them also we must ascribe such merit as pertains to the initiative in the uses to which tobacco is applied. Such evidence, however, must not be too hastily accepted; for a profoundly scientific botanist, though an altogether trustworthy authority in relation to the habitat of the plant, may be very little qualified to pronounce an opinion on the value of such Chinese monumental evidence as Dr. Meyen loosely refers to under the designation of "very old sculptures."

The Koran has been appealed to, and its modern versions even furnish the American name. A traditional prophecy of Mahomet is also quoted by Sale, which while it contradicts the assumed existence of tobacco in his time, foretells that: "in the latter days there shall be men bearing the name of moslem, but not really such, and they shall smoke a certain weed which shall be called tobacco !"\* If the prophecy did not bear on the face of it such unmistakeable evidence of being the invention of some moslem ascetic of later times, it would furnish no bad proof of Mahomet's right to the title of " the false prophet," for Sale quotes in the same preliminary discourse to his edition of the Koran, the Persian proverb "coffee without tobacco is meat without salt." An appeal to the graphic pictures of eastern social habits in the "Arabian Nights' Entertainments," furnishes strong evidence against the ancient knowledge of a custom now so universal; and in so far as such negative evidence may be esteemed of any value, the pages of our own Shakespeare seem equally conclusive, though, as will be seen, the practice had not only been introduced into England, but was becoming familiarily known before his death.

The "drinking tobacco," as smoking was at first termed, from the mode of partaking of its fumes then practiced, finds apt illustration in the language of our great dramatist. The poet, in "Timon," speaks of the sycophantish followers of the noble Athenian "through him drinking free air;" in the "Tempest" Ariel, eager in her master's service, exclaims: "I drink the air before me," and in "Antony and Cleopatra," the Egyptian Queen thus wrathfully pictures the indignities of a Roman triumph :—

<sup>\*</sup> Sale's Koran Svo. Lond. 1812. p. 164

"Mechanic slaves With greasy aprons, rules, and hammers shall Uplift us to the view; in their thick breaths, Rank of gross diet, shall we be enclouded, And forced to drink their vapour."

The references to drinking usages, moreover, are scattered plentifully through all his dramas, and intensified by the most homely and familiar illustrations, but without a single reference indicative of smoking usages; though various passages occur strikingly suggestive of such allusions, had the practice been as familiar as it became in those of younger contemporaries who survived him. In "Much Ado About Nothing," Borachio tells Don John: "being entertained for a perfumer, as I was smoking a musty room, comes in the Prince and Claudio hand in hand, in sad conference." (Act I. Scene III.) Again in "Komeo and Juliet," Romeo thus speaks of brawling love :—

> "O anything, of nothing first created ! O heavy lightness! Serious vanity ! Mis-shapen chaos of well seeming forms ! Feather of lead, bright smoke, cold\_fire, sick health !"

And again in the same scene he exclaims :---

' Love is a smoke made with the fume of sighs."

If, as Malone infers from a satire of Sir John Davis, and other early notices, tobacco was smoked by the wits and gallants on the English stage, before the close of the sixteenth century, it is difficult to evade the conclusion that such similes may have derived their force from the tobacco fumes which rose visibly in sight of the audience. These allusions and similes, however, have perhaps more resemblance in verbal form, than in embodied fancy, to the ideas now suggested; and may be deemed, after all, sufficiently independent of the smoker's " cloud" to involve no necessary association with it, even had such been familiar to the poet; but it seems to me scarcely possible that Shakespeare could have retained unmodified the language of Lady Macbeth, in the conclusion of the first act of " Macbeth," - one of the productions of his later years,-had the fumes of tobacco been so associated with wine and wassail, as they were within a very few years after the date of that wonderful drama. Encouraging her husband to "screw his courage to the sticking place," she says :--

> "His two chamberlains Will I with wine and wassail so convince, That memory, the warder of the b ain, Shall be a fume, and the receipt of reason A limbeck only."

It may be, indeed, that the recently acquired knowledge of tobacco and its *fumes*, in Europe, sufficed to prevent the poet introducing such an anachronism amid scenes of ancient Scottish story. Nevertheless, a hypercritical adherence to archæological proprieties never interferes with the graphic touches which give life to every scene of the Shakespearean drama; and that the mere anachronism would not of itself have deterred Shakespeare from an allusion to tobacco, if its unfamiliar novelty did not render it unsuitable for his purpose, may be inferred from liberties of a like kind which have proved fertile texts to many a verbal critic. The soldier's simile in the same tragedy, (Act I., Scene II.,) where he compares the royal captains, Macbeth and Banquo, to "*cannons* overcharged with double cracks;" or Sweno of Norway, disbursing his ten thousand *dollars* at Saint Colmes Inch; (Act I., Scene III.,) or Menenius, in "Coriolanus," (Act V., Scene I..) with his :--

> " Pair of tribunes that have rack'd for Rome To make *coals* ch(ap;"

or a hundred similar instances, familiar to the readers of our great dramatist, would all seem equally inadmissible were they not already there. It seems to me, however, that the association of tobacco "fumes" with "wine and wassail," a very few years later than the production of " Macbeth," would have prevented the use of the former term, in such an association in its less popular sense, as is done in that drama. The allusion there is to the rising of fumes of vapour, in distillation ; but Bacon, who, in his thirty-third essay : " Of Plantations," speaks of the tobacco of Virginia as one of the " commodities which the soil where the plantation is, doth naturally yield," elsewhere recommends "that it were good to try the taking of fumes by pipes, as they do in tobacco, of other things to dry and comfort." Here therefore, we perceive the adoption of Shakespear's term "fumes," for the smoke of tobacco within a very few years after the production of "Macbeth," a work assigned by nearly all his best editors to the reign of James I.

It is curious indeed to note how nearly we can approximate to a precise date for the literary recognition of the "Indian weed," which has been such a favourite of the student in later times. Warner, who wrote his once popular "Albion's England," in 1586, added to it three additional books in 1606, in the first of which (Book XIV. chap. 91.), a critical imp inveighs against the decline of the manners of the good old times; and among other symptoms of decay, misses the smoke of the old manor-chimney, which once gave evidence of the hospitable hearth within But, in lieu of this he notes a more perplexing smoke which "proceeds from nostrils and from throats of ladies, lords, and silly grooms," and exclaims astonished :--

"Great Belzabub! can all spit fire as well as thine ?"

But his fellow Incubus allays his fears by telling him that this novelty :---

" Was an Indian weed,

That fumed away more wealth than would a many thousands feed."

Tobacco. therefore, was not only in use, but already indulged in to an extravagant excess, in Shakespeare's later years. Though unnamed in his works, it repeatedly occurs in those of Decker, Middleton, and others of the early minor dramatists; and still more fat iliarily in those of Ben Jonson, Beaumont and Fletcher, and others of later date. In Middleton's " Roaring Girl," produced in 1611, five years before the death of Shakespeaer, and peculiarly valuable from the lively, though sufficiently coarse picture it furnishes of London manners in his day, we learn that "a pipe of smoak" was to be purchased for sixpence. In Ben Jonson's "Alchemist," of the same date, "Drugger, the tobacco man," plays a part; and a similar character figures among the dramatis personæ of Beaumont and Fletcher's "Scornful Lady." Moreover, the earliest of these notices not only refers to the costliness of the luxurious weed, with a pipe of which, Drugger bribes the Alchemist; but the allusions are no less distinct to the adulterations practised even at so early a date, and which were no doubt hinted at by Jonson in the name of his tobacconist. "Doctor" exclaims Face, the servitor, to Subtle the Alchemist, when introducing Abel Drugger to his favourable notice, (Act. I., Scene I.);---

> "Doctor, do you hear ! This is my friend Abel, an honest fellow; - , He lets me have good tobacco, and he does not Sophisticate it with sack-lees or oil, Nor washes it in muscadel and grains, Nor buries it in gravel under ground, Wrapp'd up in greasy leather, or piss'd clouts, But keeps it in fine lily pots, that open'd Smell like conserves of roses, or French beans,"

It is obvious here that, even thus early, Ben Jonson's allusions to the favourite "weed" are not to an unfamiliar novelty; though both with him, and in the later works of Beaumont and Fletcher, it is referred to invariably as a costly luxury. "Tis' good tobacco, this !" exclaims Subtle, "what is't an ounce?" and Savil, the steward, in

"The Scornful Lady" speaks ironically of "wealthy tobacco-merchants, that set up with one ounce, and break for three !" It shares indeed, with gambling, drinking, and other vices, in helping on the young spendthrifts of the drama to speedy ruin. In "Barthelomew Fair," (Act II., Scene VI,) the puritan Justice, Overdo, warns against "lusting after that tawny weed tobacco, whose complexion is like the Indian's that vents it !" and after berating it in terms scarcely quotable, he reckons the novice's outlay at "thirty pounds a week in bottle-ale, forty in tobacco !" So, too, in Beaumont and Fletcher's "Wit without Money," Valentine "a gallant that will not be persuaded to keep his estate," picturing to his faithless rivals in his love suit, the beggary that awaits them, sums up a list of the slights of fortune with : "English tobacco, with half-pipes, nor in half a year once burnt." More quaint is the allusion with which Robin Goodfellow, in "the Shepherd's Dream." (1612) fixes the introduction of the novel luxury, where reluctantly admitting the benefits of the Reformation, he bewails the exit of popery and the introduction of tobacco as concurrent events!

From this date the allusions to the use and abuse of the Indian weed abound, and leave no room to question the wide diffusion of the practice of smoking in the seventeenth century. Eurton, in his "Anatomy of Melancholy," (1621), prescribes tobacco as "a sovereign remedy to all diseases, but one commonly abused by most men;" while in Zacharie Boyd's "Last Battell of the Soule in Death," printed at Edinburgh in 1629, the quaint old divine speaks of the backslider as one with whom "the wyne pint and tobacca pype with sneesing pouder, provoking sneule, were his heartes delight !"

The term employed by Zacharie Boyd for snuff, is still in the abreviated form of "*sneeshin*," the popular Scottish name for this preparation of tobacco. There are not wanting, however, abundant proofs of the ancient use of aromatic powders as snuff, long before the introduction of tobacco to Europe. One familiar passage from Shakespeare will occur to all; where Hotspur describing the fopling lord "perfumed like a milliner," adds :---

"And 'twixt his finger and his thumb he held A pouncet-box, which ever and anon He gave his nose, and took't away again; Who, therewith angry, when it next came there Took it in snuff."

The illustration which this passage affords of the ancient use of pungent and aromatic powders in one manner in which tobacco has been so extensively employed since its introduction into Europe,

adds greatly to the force of the argument against any older employment of narcotics in the way of inhaling their fumes, based on the absence of earlier notices of so remarkable a custom. The use indeed of various narcotics, such as opium, bang : the leaf of the hemp plant, and the betel-nut, the fruit of the Areca palm, by the southeastern Asiatics appears to be traceable to a remote antiquity. Northern Europe has, in like manner, had its ledum and hop, and in Siberia. its amanita muscaria, or narcotic fungus. But the evidence fails us which should prove that in the case of the pipe, as in that of the pouncet-box, the tobacco only came as a substitute for older aromatics, or narcotics similarily employed. Nor when the evidence is looked into more carefully, are such direct proofs wanting, as suggest a comparatively recent origin, in so far as both Europe and Asia are concerned, to the peculiar mode of enjoying such narcotics by inhaling their fumes through a pipe attached to the bowl in which they are subjected to a slow process of combustion.

When engaged, some years since, in the preparation of a work on Scottish Archeology, my attention was directed, among various minor antiquities of the British Islands, to a curious class of relics popularly known in Scotland by the name of Celtic or Elfin pipes, in the north of England as Fairy pipes, and in Ireland where they are more abundant, us Danes' pipes. These are formed of white clay, with some resemblance to the form of the modern clay pipe, but variously ornamented, and invariably of a very small size compared with any tobacco-pipe in modern use. Similar relics have since been observed in England, found under circumstances calculated, like those attending the discovery of some of the Scottish examples to suggest an antiquity for them long anterior to the introduction of America's favourite narcotic, with what King James, on finding its taxability. learned to designate its "precious stink!' The most remarkable of such discoveries are those in which pipes of this primitive form have been found on Roman sites along side of genuine Roman remains. Such was the case, on the exposure, in 1852, of part of the ancient Roman wall of London, at the Tower postern ; and, along with masonry and tiles, of undoubted Roman workmanship, a mutilated sepulchral inscription was found possessed of peculiar interest from supplying the only example, so far as I am aware, in Britain, of a Christian date of the second century :--

# PO ANNO + C LXX\*

In the summer of 1853, only a few months after this London dis-

<sup>\*</sup> M.S. Letter J. W. Archer, Esq., London, April, 1853.

covery of "Fairy Pipes" along with Anglo-Roman remains of the second century, similar discoveries were made on the site of the Roman Town of Bremenium, and at one of the Forts on the wall of Hadrian, in Northumberland. The learned author of "The Roman Wall," thus refers to the discovery in the second edition of that work.\* "Shall we enumerate smoking pipes, such as those shewn in the cut, [which precisely correspond to many similar examples of the smallest size of the so called *Fairy* or *Danes' Pipes*,] among the articles belonging to the Roman period? Some of them indeed, have a medieval aspect; but the fact of their being frequently found in Roman stations, along with the pottery and other remains, undoubtedly Roman, ought not to be overlooked." After some further remarks in detail, Dr. Bruce proceeds to quote the following passage from the "Prehistoric Annals of Scotland:"—

"Another class of relics found in considerable numbers in North Berwick, as well as in various other districts, are small tobacco-pipes, popularly known in Scotland by the names of *Celtic* or *Elfin pipes*, and in Ireland, where they are even more abundant, as *Danes' pires*. To what period these curious relics belong I am at a loss to determine. The popular names attached to them, manifestly point to an era long prior to that of Sir Walter Raleigh and the maiden queen, or of the royal author of 'A Counterblast to Tobacco,' and the objects along with which they have been discovered, would also seem occasionally to lead to similar conclusions, in which case we shall be forced to assume that the American weed was only introduced as a superior substitute for older narcotics. Hemp may, in all probability, have formed one of these; it is still largely used in the east for this purpose."

When preparing the notices of miscellaneous minor Scottish antiquities, from which the above passage is abstracted, my attention had been directed, for the first time, to these relics of the old smokers' nicotian indulgences. The discovery of miniature pipes, under peculiar circumstances, had been noted in the Statistical Accounts and elsewhere, from time to time; but so far as I am aware, they had not been subjected to special notice or investigation by any previous Scottish antiquary; and finding evidence, then quoted<sup>+</sup>—of the discovery of the miniature *Elfin Pipe*, in "British encampments;" in the vicinity of a primitive monolithic monument, with flint arrow heads, stone celts, &c.: in an ancient cemetery, alongside of medieval pottery, at North Berwick; and at considerable depths in various localities; as for example, six feet in a moss between Scalloway and

<sup>\*</sup> The Roman Wall, an historical and topographical description of the Barrier of the Lower Isthmus, extending from the Tyne to the Solway; by the Rev. J. C. Bruce, M. A. Second Edition, 1853, p. 441.

<sup>†</sup> Archæology and Prehistoric Annals of Scotland, 1851, p. 680.

Lerwick, in the Orknevs; I remarked in reference to such notices that some of them were certainly suggestive of the little Elfin pipes belonging to a remote era. When, however, my esteemed friend Dr. Bruce, quoted me in seeming confirmation of, at least the possibility that the old Roman Legionary of Hadrian or Severus occasionally solaced himself with a pipe, as he kept watch and ward on the ancient barrier which in the first centuries of our era marked the outer verge of the Roman world, he took from the page just as much as sufficed to give a delicate flavor of possibility to the fancy, so pleasant to the mind of a genuine devotee of the luxurious weed, that the tobacco-pipe is a classic institution !

I doubt not but the learned Roman Antiquary of Pons Ælia, in his zeal to provide the Tungrian Legionaries of old Borcovicus, or the Spanish Varduli of Bremenium, with the consolations of a pipe, to beguile their dreary outlook from that bleak Northumbrian outpost of Imperial civilzation, most honestly and unwittingly overlooked whatever failed to square with the manifest fitness of so pleasant a conceit; nor did it ever occur to me to think of putting the old Tungrians' pipe out, by continuing the quotation, until now when, in the tardy access to British periodicals, I find myself quoted as an authority for the antiquity of the tobacco-pipe,-not only by those who, favouring such an opinion, are willing to count even the most lukewarm adherent on their side, but by others who treat me as Oliver Proudfoot, the bonnet maker, did his wooden soldan, which he set up merely for the pleasure of knocking it down; or as the gallant Bailie and bonnet maker of Saint Johnstoune says: "Marry, and sometimes 1 will place you a bonnet (an old one most likely,) on my soldan's head, and cleave it with such a downright blow, that in troth, the infidel has but little of his skull remaining to hit at !" Far be it from me to interfere with the practice of those who, like the valiant bonnet maker, wish to make themselves familiar with the use of their weapon on such easy terms, even though, perforce, made the wooden soldan on which it is applied; but I must confess to a decided objection to being held responsible for opinions quoted only for the purpose of relutation, when as it would seem, these are read through such a refracting medium as the Roman spectacles of an antiquary, who may be assumed without any disparagement to be a little wall-eyed.

Quotations at second hand are never very trustworthy, and it seems difficult to credit with more direct knowledge than such as may be derived from the partial quotation in the "Roman Wall," such

writers as one in the Archaelogical Journal,\* who, after referring to Mr. Crofton Croker's signal refutation of "this absurd notion," couples me with Dr. Bruce as " inclined to assign such pipes to an age long prior to that of Elizabeth and Sir Walter Raleigh." It might be unreasonable to blame a contributor of editorial notes to the Archeological Journal for overlooking a paragraph in the Proceedings of the Scottish Antiquaries, of date a year earlier than his note.+ which records that "Dr. Wilson communicated a notice of the discovery of various of the small tobacco-pipes popularly termed 'Celtic' or 'Elfin pipes,' in digging the foundation of a new school house at Bonnington, in the immediate vicinity of Edinburgh. Along with these were found a quantity of bodles or placks of James VI., which he exhibited with the pipes, and at the same time expressed his belief that they probably supplied a very trustworthy clue to the date of this somewhat curious class of minor antiquities." This more matured opinion of 1853 lay out of the way, and might not be noticed by the Archæological Journalist, as it would assuredly have been overlooked by the zealous Roman, quite as much as the follow-ing continuation of the original quotation so aptly abridged to the proportions of his classic tunic. But any writer who looked in its. own pages, for the opinions set forth on this subject, in the "Prehistoric Annals of Scotland," would have found that the abbreviated. quotations in the "Roman Wall" and elsewhere, only give one side of the statement, and that, after referring to an article in the Dublin Penny Magazine, the inquiry is thus summed up :--

"The conclusion arrived at by the writer in that magazine is, that these Danes' pipes are neither more nor less than tobacco pipes, the smallest of them pertaining to the earliest years of Queen Elizabeth's reign, when the rarity and value of tobacco rendered the most diminutive bowl sufficiently ample for the enjoyment of so costly a luxury. From this he traces them down to the reign of Charles II. by the increasing dimensions of the bowl. It is not improbable that these conclusions may be correct, notwithstanding the apparent indications of a much earlier origin, which circumstances attendant on their occasional discovery have seemed to suggest.

The following description of a curious Scottish memorial of the luxury would, however, seem at least to prove that we must trace the introduction of tobacco into this country to a date much nearer the discovery of the new world by Columbus than the era of Raleigh's colonization of Virginia. The grim old keep of Cawdor Castle, associated in defiance of chronology with King Duncan and Macbeth. is augmented like the majority of such Scottish fortalices, by additions of the sixteenth century. In one of the apartments of this latter erection, is a stone

<sup>\*</sup> Archæological Journal, Vol. XI, p. 182.

<sup>†</sup> Proceedings S. A. Scot. Vol. I. p. 182.

chimney, richly carved with armorial bearings and the grotesque devices common on works of the period. Among these are a mermaid playing the harp, a monkey blowing a horn, a cat playing a fiddle, and *a fox smoking a tobacco pipe*. There can be no mistake as to the meaning of the last lively representation, and on the same stone is the date 1510, the year in which the wing of the castle is ascertained to have been built,"\* and in which it may be added, Jamaica was settled by the Spaniards.

Having thus even at the very first,-while "at a loss to determine to what period the curious relics called Dane's or Elfin pipes belonged," and consequently avoiding a dogmatic assertion on a subject "left for further investigation,"-furnished a tolerably significant indication of my inclination to assign to such nicotian relics a post-Columbian introduction to Britain; and having, moreover, at a later period given unequivocal expression of a confirmed opinion of their modern origin: I was somewhat surprised to find myself, not very long since, figuring alongside of a singularly creditable array of chivalrous archaeologists, all knights of the ancient tobacco pipe, and ready to shiver a lance with any puny modern heretic who ventured to question that Julius Cæsar smoked his merchaum at the passage of the Rhine, or that Herodotus partook of a Scythian peace-pipe when gathering the materials for the birth of History! Here is the array of learned authorities, clipped out of a recent English periodical. produced as it will be seen, to answer in the affirmative, that the ancients did smoke : Scythian and Roman, Celt, Frank, and Norman !

DID THE ANCIENTS SMOKE ?- The question as to whether smoking was known to the ancients has just been started in Germany by the publication of a drawing contained in the Recueil des Antiquités Suisses of Baron de Bonstetten, which represents two objects in clay, which the author expressly declares to be smoking pipes. The authors of the "History of the Canton of the Grisons" had already spoken of these objects, but classified them among the instruments made use of by the soothsayers. The Abbé Cochet, in his work on Subterranean Normandy, mentions having found similar articles either whole or in fragments, in the Roman necropolis near Dieppe, which he at first considered as belonging to the seventeenth century, or perhaps to the time of Henri III. and Henri IV, The Abbé, however, afterwards changed his opinion on reading the work of Dr. Collingwood Bruce, entitled "The Roman Wall," in which the author asks the question whether the pipes discovered at. Pierce Bridge, in Northumberland, and in London, at places where Roman stations were known to have existed, belonged to the Romans ? Dr. Wilson, in his Archæology of Scotland, states that tobacco was only introduced as a superior kind of narcotic, and that hemp was already known to the ancients as a sedative. The pipes found in Scotland by Dr. Wilson might have served for using this latter substance. M. Wœchter, in his "Celtic Monuments of Hanover," says that clay pipes from 6 to 8 inches in length had been found in tombs at

<sup>\*</sup> Archæology and Prehistoric Annals of Scotland, p. 681. The Cawdor sculpture and date are described on the authority of Mr. Caruthers, a very trustworthy observer.

Osnabruck, which proved that the ancients smoked. M. Keferstein, in his "Celtic Antiquities," boldly declares that the Celts smoked. Klemm, in his "History of Christian Europe," states that the smoking of intoxicating plants was known to the Scythians and Africans long before the introduction of tobacco into Europe. Herodotus, in speaking of the Scythians, does not go quite so far, but mentions that the people spread hemp seed on red-hot stones and inhaled the vapour sent forth. It is therefore thought by Baron de Bonstetten that the pipes of which he gives the drawing were used before the introduction of tobacco into Europe.\*

This is by no means the first time that classic authorities have been quoted in proof of the antiquity of smoking. In the Anthologia Hibernica, + for example, a learned treatise aims to prove, on the authority of Herdotus (lib. I. Sec. 36,) Strabo, (lib. vii. 296), Pomponius Mela, (2.) and Solinus (c. 15,) that the northern nations of Europe were acquainted with tobacco, or an herb of similar properties, long before the discovery of America, and that they smoked it through small Pliny has also been produced to show that Coltsfoot tubes. (tussilago farfara, a mucilagenous and bitter herbaceous plant, the leaves of which were once in great favor for their supposed medicinal qualities.) furnished a substitute for the American plant which superseded this and other fancied supplies of the ancients' pipes. Speaking of that plant as a remedy for a cough, (Nat. Hist. xxvi. 16.) Pliny says :-- "Hujus aridæ cum radice fumus per arundinem, haustus et devoratus, veterem sanare dicitur tussim ; sed in singulos haustus passum gustandum est." This, however, is nothing more than a proof of the antiquity of a process of applying the fumes or steam of certain plants, for medicinal purposes, which is recommended in a treatise on "the Vertues of Colefoot" in the Historie of Plantes, by Rembert Dodoens, translated and published in England in 1578, "The parfume of the dryed leaves" says he, "layde upon quicke coles, taken into the mouth through the pipe of a funnell, or tunnell, helpeth suche as are troubled with the shortness of winde, and fetche their breath thicke or often." So far, how-

<sup>\*</sup>Quoted in the North British Daily Mail, July 24th, 1856, but without naming the original source. It was copied into the *Illustrated Times*, of July 26th, and by other periodicals, but there also without reference to the original authority. In this case I cannot doubt that the writer who thus loosely quotes, or misquotes, the "Archæology of Scotland" does it at second hand, from Dr. Bruce.

**<sup>†</sup>** Vol. I., p. 352 quoted in *Notes and Queries*, X. 48. The subject has been handled in all lights, and each view of the questions it involves has found its defenders in this useful periodical,-doubly useful to those who are cut off from the great public libraries. In N. and Q., vol. II., p. 154, much curious information is concisely given relative to the assumed use of tobacco, anciently, and in the East. Ibid p. 150. Its Eastern antiquity finds a contradiction on the authority of Lane, and still more of Dr. Meyer of Konigsberg, who discover d in the works of an old Hindostance physician, a passage in which tobacco is distinctly stated to have been introduced into India, by the Frank nations, in the year 1609.

ever, is this ancient process from indicating a mode of inhaling herbs, in any sense equivalent to the American luxury by which it may be supposed to have been superseded, that it is by no means banished, even now, from the practise of ancient female herbalists and domestic mediciners, whom I have known recommend the inhalation of the fumes or steam of various plants, not by means of a tobacco pipe, but through the spout of a teapot !

There is no question, however, that many plants have been employed as substitutes for tobacco, since the introduction of the practice of smoking. The slight astringency and diuretic qualities of polytrichum and other Bryaceæ, led to their use formerly in medicines. and the practice was once common, as I have been assured, in Annandale, and other border districts of Scotland, and is not even now wholly obsolete, of smoking the dried sphagnum latifolium, or the obtusifolium and others of the mosses which abound in the marshy bogs. So also the millefolium or yarrow, one of the various species of the genus Achillea, and several of the herbs which from their shape and the velvet surface of the leaves, are popularly known by the name of mouse ear, have long supplied to the English rustic an economic substitute for tobacco; just as the sloe, hawthorn, sage, and other leaves have furnished a native apology for the tea plant. But the "time immemorial" to which such practice extends probably falls far short of well ascertained dates when tobacco and the tobacco pipe were both recognized as gifts of the new world to the old. But it is curious to note, that one of the most anciently accredited substitutes for tobacco : the coltsfoot, appears to have been employed to adulterate it almost as soon as it came into use in England. Dame Ursla, in Ben Jonson's "Bartholomew Fair," (1614,) thus addresses her dull tapster :-- " I can but hold life and soul together with this, and a whiff of tobacco at most, where's my pipe now? not filled, · · · Look too't sirrah, you were thou errant incubee! best; threepence a pipe full, I will ha' made, of all my whole halfpound of tobacco, and a quarter of a-pound of coltsfoot mix't with it too, to itch [eke] it out. I that have dealt so long in the fire will not be to seek in smoke now."

The libraries of Canada furnish very slender means for dallying with the Bibliography of the nicotian art. But some of the references made above may be thought to bear on the subject, and the very terms in which the royal author of the "Counterblaste" assails it as a novelty of such recent origin "as this present age can very well remember both the first author and forms of its introduction," seem

sufficiently clear evidence that smoking was unknown to Europe before the discovery of this continent. Spain doubtless first enjoyed the novel luxury; probably-at the latest,-not long after the commencement of the sixteenth century. The year 1560 is assigned for its introduction into France, and most commonly that of 1586,in which Admiral Drake's fleet returned from the attack on the west Indian Islands-for its reaching England. But though in all probability only beginning at these dates to attract special attention, the custom of smoking tobacco can scarcely be supposed to have remained unknown to the Spaniards before the close of the fifteenth century, or to have failed to have come under the notice both of French and Englishmen at an early period thereafter. When at length fairly introduced into England, it met with a ready welcome. So early as 1615, we find the popular poet, Joshua Sylvester following in the wake of the royal counterblast, with his :-- " tobacco battered, and the pipes shattered about their ears that idly idolize so base and barbarous a weed, or at leastwise overlove so loathsome a vanity, by a volley of holy shot thundered from Mount Helicon,"-tolerable proof of the growing favour for the "weed." The plant itself was speedily brought over and cultivated in various districts, till prohibited by an act of Parliament; and Pepys, in his Diary,-referring to Winchcombe, in Gloucestershire, where tobacco is affirmed to have been first raised in England,-under the date, September 19th, 1667, mentions the information communicated to him by his cozen, Kate Joyce: "now the life-guard, which we thought a little while since was sent down into the country about some insurrection, was sent to Winchcombe, to spoil the tobacco there, which it seems the people there do plant contrary to law, and have always done, and still been under force and danger of having it spoiled, as it hath been oftentimes, and yet they will continue to plant it "\*

Another entry of the same indefatigable diarist, furnishes evidence not only of the early faith in the anti-contagious virtues of tobacco, but also of the no less early mode of using it in England according to a fashion which is now more frequently regarded as a special prerogative of young America. On the 7th of June, 1665, Pepys notes that the first sight of the plague-cross, with its accompanying solemn formula of prayer, moved him, not to a devotional ejaculation, as might perhaps seem most fitting, but only to chew tobacco! "The hottest day," he writes, "that ever I felt in my life. This day, much against my will, I did in Drury Lane, see two or three houses marked

<sup>\*</sup> Pepys' Diary, 4th Edition. Vol. III., p. 252.

with a red cross upon the doors, and 'Lord have mercy upon us!' writ there; which was a sad sight to me, being the first of the kind that, to my remembrance I ever saw. It put me in an ill conception of myself and my smell, so that I was forced to buy some rolltobacco to smell to and chaw, which took away the apprehension.'\*\*

The costly nature of the luxury has been assumed as furnishing ample explanation alike of the minute size of the original tobacco pipe,- which in all probability secured for it in later times its designation of "Elfin" or "Fairy Pipe."-and of the early substitution of native pungent and fragrant herbs for the high priced foreign weed. The circumstances, however, which render the rarer English literature of the sixteenth and seventeenth centuries inaccessible here, have furnished resources of another kind which may perhaps be thought to account for this on other, and no less probable grounds. During a visit to part of the Minnesota Territory, at the head of Lake Superior, in 1855, it was my good fortune to fall in with a party of the Saultaux Indians,—as the Chippeways of the far west are most frequently designated, - and to see them engage in their native dances, in footraces, and other sports, and among the rest : in the luxury of the pipe. It is scarcely necessary to remark that the Indian carries his pipe-stem in his hand, along with his bow, tomahawk, or other weapon, while the pipe itself is kept in the tobacco pouch, generally formed of the skin of some small animal, dressed with the fur, and hung at his belt. But what struck me as most noticeable was that the Indians in smoking, did not exhale the smoke from the mouth, but from the nostrils; and this, Mr. Paul Kane assures me is the universal custom of the Indians of the north west, among whom he has travelled from the Red River settlement to the shores of the Pacific. By this means the narcotic effects of the tobacco are greatly increased, in so much so that a single pipe of strong tobacco smoked by an Indian in this manner, will frequently produce complete giddiness and intoxication. The Indians accordingly make use of various herbs to mix with and dilute the tobacco, such as the leaf of the cranberry, and the inner bark of the red willow, to both of which the Indian word kinikinik is generally applied, and the leaves of the winterberry, which receives the name of *pahgezegun*. † The cranberry

<sup>\*</sup> Pepy's Diary, 4th Edition. Vol. II., p. 242.

<sup>&</sup>lt;sup>†</sup>I am informed by the Rev. Dr. O'Meara, the translator of the Bible in the Chippeway tongue, that the literal significance of *kinikinik* is "he mixes." *kinikangun* is "a mixture," and the words are applied by the Indians not to the diluent alone, but to the tobacco and diluents when mixed and prepared for use. So also *pakyezegun* is "anything mixed," and may be rendered: something to mix with tobacco.

and winterberry leaves are prepared by passing them through the top of the flame, or more leisurely drying them over the fire, without allowing them to burn. Among the Creeks, the Chocktaws, and other Indians in the south, the leaves of the sumach, prepared in a similar manner, answer the like purpose. The leaf of the winterberry, or tea berry, (coltheria procumbens,) has a pleasant aroma, which may have had some influence on its selection. The Indians of the north west ascribe to it the further property of giving them wind, and enabling them to hold out longer in running; but the main object of all such additions appears to be to dilute the topacco.and thereby admit of its prolonged enjoyment. Having both chewed and smoked the winterberry leaf prepared by the Indians, I am able to speak positively as to the absence of any narcotic qualities, and I presume that with it and all the other additions to the tobacco, the main object is to provide a diluent, so as to moderate the effects, and prolong the enjoyment of the luxury. The same mode is employed with ardent spirits. Mr. Kane remarks of the Chinook Indians: it is a matter of astonishment how very small a quantity of whisky suffices to intoxicate them, although they always dilute it largely in order to prolong the pleasure they derive from drinking.

The custom of increasing the action of the tobacco fumes on the nervous system, by expelling them through the nostrils, though now chiefly confined to the Indians of this continent, appears to have been universally practised when the smoking of tobacco was introduced into the old world. It has been perpetuated in Europe by those who had the earliest opportunities of acquiring the native custom. The Spaniard still expels the smoke through his nostrils, though using a light tobacco, and in such moderation as to render the influence of the narcotic sufficiently innocuous. The Greek sailors in the Levant very frequently retain the same practice, and with less moderation in its use. Melville also describes the Sandwich Islanders, among whom tobacco is of such recent introduction, as having adopted the Indian custom, whether from imitation or by a natural savage instinct towards excess ; and evidence is not wanting to prove that such was the original practice of the English smoker. Paul Hentzner, in his " Journey into England." in 1598,\* among other novelties describes witnessing at the playhouse, the practice, as then newly borrowed from the Indians of "Here," he says, "and everywhere else, the English are Virginia.

<sup>\*</sup>Malone quotes from epigrams and satires of the same date,—eighteen years before the death of Shakespear,—to prove that playgoers, even at so early a date, were attended by pages, with pipes and tobacco, which they smoked on the stage, where the wits were then wont to sit. Vide Notes and Queries, vol. X., p. 49.

constantly smoking of tobacco, and in this manner: they have pipes on purpose made of clay, into the further end of which they put the herb, so dry that it may be rubbed into powder, and putting fire to it, they draw the smoke into their mouths, which they puff out again through their nostrils, like funnels, along with it plenty of phlegm, and defluxion of the head."

To this it is, that Justice Overdoo refers in Ben Jonson's "Bartholomew Fair." (Act II., Scene VI.) "Nay, the hole in the nose here, of some tobacco-takers, or the third nostril, if I may so call it, which makes that they can vent the tobacco out, like the ace of clubs, or rather the flower-de-lice, is caused from the tobacco, the mere tobacco!" and so also, in a passage already referred to, in Warner's "Albion's England," the "Indian weed fumes away from nostrils and from throats" of ladies, as well as lords and grooms.

The minute size of the most ancient of the British tobacco pipes which has led to their designation as those of the Elves or Fairies, may therefore be much more certainly ascribed to the mode of using the tobacco, which rendered the contents of the smallest of them a sufficient dose, than to any economic habits in those who indulged in the novel luxury. In this opinion I am further confirmed by observing the same miniature characteristics mark various specimens of antique native pipes of a peculiar class to which I have already referred as found in Canada, and which appear to be such as, in all probability were in use, and furnished the models of the English clay pipes of the sixteenth century. But if the date thus assigned for the earliest English clay pipes be the true one, it has an important bearing on a much wider question; and as a test of the value to be attached to popular traditions, may suggest the revision of more than one archæological theory based on the trustworthiness of such evidence. A contributor to "Notes and Queries,"\* quotes some dogrel lines printed in the "Harleian Miscellany" in 1624, where speaking of the good old times of King Harry the Eighth, smoking is thus ludicrously described as a recent novelty :---

> "Nor did that time know To puff and to blow, In a piece of white clay As you do at this day, With fier and coale And a leafe in a hole !"

These lines are ascribed in the original to Skelton, who died in 1529, and by a course of reasoning which seems to run somewhat in

<sup>\*</sup>Notes and Queries. Vol. VII., p. 230.
a circle, it is assumed that they cannot be his, because tobacco was not introduced into England "till 1565 or thereabouts." Brand in his "Popular Antiquities," ascribes its introduction to Drake in 1586; while the old keep at Cawdor, already referred to, with its sculptured reynard and his pipe, would carry it back to 1510, and by implication still nearer the fifteenth century. So peculiar a custom as smoking, would no doubt, at first be chiefly confined to such as had acquired a taste for it in the countries from whence it was borrowed, and until its more general diffusion had created a demand for tobacco, as well as for the pipe required for its use, the smoker who had not acquired an Indian pipe along with the "Indian weed," would have to depend on chance, or his own ingenuity, for the materials requisite for its enjoyment. Hence an old diarist writing about 1680, tells us of the tobacco smokers :---" They first bad silver pipes, but the ordinary sort made use of a walnut shell and a straw. I have heard my grandfather say that one pipe was handed from man to man round the table. Within these thirty-five years 'twas scandalous for a divine to take tobacco. It was then sold for its weight in silver. I have heard some of our old yeomen neighbours say, that when they went to market they culled out their biggest shillings to lay in the scales against the tobacco; now the customs of it are the greatest his majestie hath." In the interval between the primitive walnut-shell pipe, or the single clay pipe for a whole company to partake of the costly luxury, and this later era of its abundant use, the supply of pipes had, no doubt, kept pace with that of the tobacco, and they had undergone such alterations in form as were requisite to adapt them to its later mode of use. Their material also had become so uniform, and so well recognised, that a clay pipe appears to have been regarded, in the seventeenth century as the sole implement applicable to the smoker's art. An old string of rhymed interogatories, printed in Wit's Recreations, a rare miscellany of 1640, thus quaintly sets forth this idea:---

> "If all the world were sand, Oh, then what should we lack'o; If as they say there were no clay, How should we take tobacco?"

Towards the latter end of the sixteenth, and in the early years of the seventeenth century, under any view of the case, small clay pipes, such as Teniers and Ostade put into the mouths of their Boors, must have been in common use throughout the British Islands. They have been dredged in numbers from the bed of the Thames, found in

abundance on various sites in England and Ireland, where the soldiers of the parliament and revolution encamped; and in Scotland in divers localities from the border, northward, even to the Orkneys, They have been repeatedly met with in old Churchyards, and turned up in places of public resort. Occasionally too, to the bewilderment of the antiquary, they are discovered in strange propinquity to primitive, Roman, and medieval relics,-but in a sufficient number of cases with such potters' stamps on them as suffice to assign these also to the sixteenth and seventeenth centuries. At a date so comparatively recent as that of the revolution of 1688, they must have been nearly as familiar throughout Britain and Ireland, as the larger clay pipe of the present day: and yet towards the end of the eighteenth century we find them described in Scottish statistical reports as "Elfin pipes ;" and when at a later date, they attract a wider attention, it is found that, in total independence of each other, the peasantry of England, Scotland, and Ireland, have concurred in ascribing these modern antiques to the Danes, the Elves and the Fairies! I must confess that the full consideration of all the bearings of this disclosure of the sources of modern popular belief has greatly modified the faith I once attached to such forms of tradition as memorials of the past. The same people who, by means of Welsh triads, genealogical poems, like the Duan Albannach and Eireannach, and historical traditions, like the memory of the elder home of the Saxons in the Gleeman's song, could transmit, by oral tradition alone, the chronicles of many generations, now depend so entirely on the chroniclings of the printing press, that they cannot be trusted with the most familiar traditions of a single century. This no doubt only applies to very modern centuries; but the treacherousness of the historical memory of a rude savage people is sufficiently illustrated be the fact that we search in vain among the Indians of this continent for any tradition of the first intrusion of the white man.

A few general remarks on the varying characteristics of the pipes anciently constructed, or now in use among the Indian tribes of North America will not be out of place here, as a means of illustrating the customs and ideas associated at various times, and among different tribes, with the peculiar rites and usages of the pipe as the special characteristic of the new world. For some of the facts relating to the Indians of the north west, I am indebted to the Rev. Dr. O'Meara, missionary among the Chippeways; to Dr. George Beattie, formerly United States Indian Agent of the Winnebagos, —who have since been driven to desert their old hunting grounds in Wisconsin for the far west, and from their rapidly diminishing numbers, cannot long survive as a distinct tribe,—and also, in special reference to those of the remote north west, and on the shores of the Pacific, to Mr. Paul Kane, along with the information derived from inspecting a fine collection of Indian relics secured by him during three years travel in the Hudson Bay Company's Territory, and among the neighbouring tribes within the territories of the United States. A comparison of the facts thus obtained with some of the conclusions arrived at by others from the examination of the older traces of the custom and usages of smoking, appear calculated to throw some additional light on the latter, and especially to modify the opinion derived from the investigation of examples of the ancient arts of the Mound Builders, and other aboriginal traces of this continent.

Insignificant, and even puerile, as the subject of the tobacco pipe appears, it assumes an importance in many respects only second to that of the osteological remains of the ancient races of this continent when viewed as part of the materials of its unwritten history. In Messrs. Squier and Davis' valuable " Contribution to Knowledge"\* the tobacco pipes found in the ancient sepulchral mounds of the Mississippi Valley are specially noted as constituting not only a numerous, but a highly interesting class of remains, on the construction of which the artistic skill of their makers seems to have been lavished with a degree of care and ingenuity bestowed on no other works. "They are sculptured into singular devices: figures of the human head, and of various beasts, birds, and reptiles. These figures are all executed in miniature, but with great fidelity to nature." Thus, for example, the authors remark in reference to one pipe-head (Fig. 183, p. 268,) carved in the shape of a toad: the knotted, corrugated skin is well represented, and the sculpture is so very truthful that if placed in the grass before an unsuspecting observer, it would probably be mistaken for the natural object; and they further add : "those who deem expression in sculpture the grand essential, will find something to amuse as well as to admire, in the lugubrious expression of the mouths of these specimens of the toad." The same writers again remark, in describing the immense deposit of pipes found on the "altar" of one of the great mounds in the Scioto Valley, some of them calcined, and all more or less affected by the fires of the ancient ceremonial of cremation or sacrifice :--- " The bowls of most of the pipes are carved in miniature figures of animals,

<sup>\*</sup> Ancient Monuments of the Mississippi Valley, pages 228, 229.

birds, reptiles, &c. Not only are the features of the various objects represented faithfully, but their peculiarities and habits are in some degree exhibited. The otter is shewn in a characteristic attitude, holding a fish in his mouth; the heron also holds a fish; and the hawk grasps a small bird in its talons, which it tears with its beak. The panther, the bear, the wolf, the beaver, the otter, the squirrel, the racoon, the hawk, the heron, crow, swallow, buzzard, the paroquet, toucan, and other indigenous and southern birds; the turtle, the frog, toad, rattlesnake, etc., are recognised at first glance."\* To this comprehensive list Mr. Squier makes further additions in a work of later date. Contrasting the truthfulness of the carvings from the mounds with the monstrosities or caricatures of nature usually produced by the savage sculptor, he remarks: "they display not only the general form and features of the objects sought to be represented, but to a surprising degree their characteristic expression and attitude. In some instances their very habits are indicated. Hardly a beast, bird, or reptile, indigenous to the country is omitted from the list;" and in addition to those named above, he specifies the elk, the opossum, the owl, vulture, raven, duck, and goose, and also the alligator. + Of no less interest are the numerous examples of sculptured human heads, some of them presenting striking traits of individual portraiture, and which are assumed, from the minute accuracy of many of the accompanying sculptures of animals, to furnish faithful representations of the predominant physical features of the ancient people by whom they were made.

Compared with the monuments of Central and Southern America, the sculplured façades of the temples and palaces of Mexico and Peru, the friezes adorned with hieroglyphics, the kalendars, and colossal statues of gods and heroes, of Yucatan: the art which found its highest object in the decoration of a pipe-bowl is apt to appear insignificant enough. Nevertheless, the simplicity, variety, and expression of these miniature works of art, their evidence of great imitative skill, as well as of delicacy of execution, all render them just objects of interest and careful study. But high as is the value which attaches to them as examples of the primitive æsthetic arts of this continent, they have a still higher significance in relation to ethnological inquiries. By the fidelity of their representations of so great a variety of objects derived from the animal kingdom, they furnish evidence of a knowledge, possessed by these ancient artists of the

<sup>\*</sup> Ancient Monuments of the Mississippi Valley. Page 152.

<sup>&</sup>lt;sup>†</sup>Antiquities of the State of New York. Page 338.

Mississippi Valley, of the fauna peculiar not only to southern, but to tropical latitudes, suggestive either of arts derived from a foreign source, and of an intimate intercourse maintained with the central regions where the civilization of ancient America attained its highest development, or else indicative of a migration from the south, and an intrusion into the northern area of the continent, of the race of the ancient graves of Central America, bringing with them into their new area the arts of the tropics, and models derived from the animals familiar to their fathers in the parent-land of the race.

That such a migration,- rather than a contemporaneous existence of the same race over the whole area thus indicated, and maintaining intimate intercommunication and commercial intercourse, is the more probable inference, is suggested on various grounds. If the Mound Builders had some of the arts and models, not only of Central America, but of Peru, they had also the native copper of Lake Superior, and mica believed to be traceable to the Alleghanies, while the gigantic tropical shells of the Gulf of Mexico have been found alike in these ancient mounds and in the graves along the shores of Lake Huron and Georgian Bay. The fact indeed that among the specimens of their most elaborate carving, some of the objects represent birds and quadrupeds belonging to latitudes so far to the south. naturally tends to suggest the idea of a central region where the arts were cultivated to an extent unknown in the Mississippi regions, and that those objects manufactured in the localities where such models are furnished by the native fauna, remain only as the evidences of ancient commercial relations maintained between these latitudes and the localities where now alone such are known to abound. But in opposition to this, full value must be given to the fact that neither the relics, nor the customs which they indicate. appear to pertain exclusively to southern latitudes, nor are such found to predominate among the singular evidences of ancient and more matured civilization either in Central or Southern America, while the varied nature of the materials employed in the arts of the Mound Builders, indicate a very wide range of relations; though it cannot be assumed that these were maintained in every case by direct intercourse.

The earlier students of American Archæology, like the older Celtic Antiquaries of Britain; gave full scope to a system of theorising which built up comprehensive ethnological schemes on the very smallest premises; but in the more judicious caution of later writers there is a tendency to run to the opposite extreme. Dr. Schoolcraft

certainly manifests a disposition to underrate the artistic skill unmistakably discernable in some of the works of the Mound Builders : while Mr. Haven solves the difficulty by referring such evidences of art to an undetermined foreign source. After describing the weapons, pottery, and personal ornaments obtained from the mounds, the latter writer adds, "and, with these were found sculptured figures of animals and the human head, in the form of pipes, wrought with great delicacy and spirit from some of the hardest stones. The last-named are relics that imply a very considerable degree of art, and if believed to be the work of the people with whose remains they are found, would tend greatly to increase the wonder that the art of sculpture among them was not manifested in other objects and places. The fact that nearly all the finer specimens of workmanship represent birds or land and marine animals belonging to a different latitude, while the pearls, the knives of obsidian, the marine shells, and the copper, equally testify to a distant, though not extra-continental origin, may however exclude these from being received as proofs of local industry and skill."\* A reconsideration of the list already given of animals sculptured by the ancient pipe-makers of the mounds, as quoted from the narrative of Messrs. Squier and Davis, along with the later additions of the former, set forth in a form still less in accordance with such deductions, will, I conceive, satisfy the inquirer that it is quite an over statement of the case to say that nearly all represent animals belonging to a different latitude. The real interest, and difficulty of the question lies in the fact of discovering, along with so many spirited sculptures of animals pertaining to the locality, others represented with equal spirit and fidelity, though belonging to different latitudes. On this subject, familiarity with early British antiquities induces me to regard such an assignment of all the sculptures of the mounds to a foreign origin, on account of their models being in part derived from distant latitudes, as a needless assumption which only shifts without lessening the difficulty. On the sculptured standing stones of Scotland-belonging apparently to the closing era of paganism, and the first introduction of christianity there, - may be seen the elephant, the camel, the tiger or leopard, the ape, the serpent, and other representations or symbols, borrowed, not like the models of the Mound Builders, from a locality so near as readily to admit of the theory of direct commercial intercourse, but some of them from the remote extreme of Asia. The only difference between the imitations of the foreign

<sup>\*</sup> Haven's Archæology of the United States. Page 122.

fauna of the Scottish and the ancient American monuments, is that the former occasionally betray, as might be expected, the conventional characteristics of a traditional type,\* while the latter, if they furnish evidence of migration, prove it to have been recent, and to a locality not so distant as to preclude all renewal of intercourse with their ancestral birth-land.<sup>+</sup> Notwithstanding the great spirit displayed in many of the miniature sculptures of the Mound Builders, however, the difference in point of fidelity of imitation between them and the carvings of foreign subjects on the Scottish standing stones though unmistakeable, is not so great as the descriptions of American Archæologists would suggest: while both are alike accompanied by the representations of monstrosities or ideal creations of the fancy, which abundantly prove that the ancient sculptors could work without a model. Some of the human heads of the American sculptures for example, if regarded as portraits, must be supposed to be designed in the style of Punch !; and several of the animals figured in " The Ancient Monuments of the Mississippi Valley," e. g. the wild cat. Fig. 158; the "very spirited, though not minutely accurate head of the Elk," Fig. 161, and the supposed "cherry birds," Figs. 174. 175, of one of which it is remarked: "nothing can exceed the lifelike expression of the original;" fall far short of the fidelity of imitation ascribed to them in the accompanying text.

It has been noted by more than one American Archæologist as a singular fact that no relics obviously designed as idols, or objects of worship, have been dug up in the mounds, or found in such circumstances as to connect them with the religious practices of the Mound Builders. But the very remarkable characteristics of their elaborately sculptured pipes, and the obviously important part they appear to have played in the services accompanying the rites of sacrifice or cremation, and the final construction of the gigantic earth-pyramids

<sup>†</sup>Vide Archæology and Prehistoric Annals of Scotland. Page 501, and Dr. Wise's Notes on Buddhist Opinions and Monuments. Transactions of R.S.E. Vol. XXI. Page 255.

<sup>‡</sup>Vide Davis and Squier's Ancient Monuments, Fig. 145, described as the most beautiful of the series, and a head, the workmanship of which is unsurpassed by any specimen of ancient American Art, not excepting the best productions of Mexico and Peru, fully bears out these remarks. But in contrast with it may be placed Figs. 143, 146 and 148; and as a still stronger illustration of how far the enthusiasm of the most careful observers may lead them compare Fig. 75, page 193, with the description which says of it: "the attitude is alike natural and spirited l"

<sup>\*</sup> It is worthy of note that the objects least truthfully represented among the sculptures of the Mound Builders, also, in some cases at least, appear to be those of animals foreign to the region, e. g. the Toucan (?) "Ancient Monuments of the Mississippi Valley;" Fig. 169, page 260; which might have been better described as a Raven; and Fig. 178, also a Toucan, but much more of a traditional than truthful portraiture.

which have given the name to the race that furnished the artists by whom they were wrought, all tend to suggest very different associations with the pipe of those ancient centuries from such as now pertain to its familiar descendant. It has accordingly been supposed that the elaborate employment of the imitative arts on the pipeheads found deposited in the mounds, indicate their having played an important part in the religious solemnities of the ancient race, among whom the number of such relics proves that the practice of smoking was no less universal than among the modern Indians. The conjecture that this practice was more or less interwoven with the primitive civil and religious observances of America is thus illustrated by the authors already quoted,\* from the more modern customs and ideas connected with it: "the use of tobacco was known to nearly all the American nations, and the pipe was their grand diplomatist. In making war and in concluding peace it performed an important part. Their deliberations, domestic as well as public, were conducted under its influences, and no treaty was ever made unsignalized by the passage of the calumet. The transfer of the pipe from the lips of one individual to those of another was the token of amity and friendship, a gage of honor with the chivalry of the forest which was seldom violated. In their religious ceremonies, it was also introduced with various degrees af solemnity. The custom extended to Mexico, where, however, it does not seem to have been invested with any of those singular conventionalities observed in the higher latitudes. It prevailed in South America and the Caribbean Islands."

To be continued.

# ON THE OCCURRENCE OF THE GENUS CRYPTOCERAS IN SILURIAN ROCKS.

BY E. J. CHAPMAN,

PROFESSOR OF MINERALOGY AND GEOLOGY IN UNIVERSITY COLLEGE, TORONTO.

### Read before the Canadian Institute, 18th April, 1857.

But one living genus of the chamber-shelled cephalopods being known, the classification of the numerous fossil types met with more particularly in the Palæozoic and Secondary rocks, is of necessity

<sup>\*</sup> Ancient Monuments of the Mississippi Valley. Page 229.

based on characters derived immediately from the shell itself. For the purpose of classification, four characters, of more or less value, are especially available. These comprise:—(1) the character of the aperture; (2) the form of the septa; (3) the position and character of the siphuncle; and (4) the form and mode of growth of the shell.

The aperture may be: (a) open; (b) contracted. The septa: (a) simple; (b) angular or lobed. The position of the siphuncle: (a) central or sub-central; (b) internal or "ventral;" (c) external or "dorsal." The siphuncle itself: (a) simple; (b) complicated. The form of the shell: (a) straight or conical; (b) arched or "horned" in various ways; (c) discoidal, with or without contiguous volutions; and (d) spiral.

By means of these characters, all the trustworthy genera of the chambered cephalopods may be arranged, conveniently at least, if not naturally, in ten sections or families\*: as shewn in the following: tabular view:—

1. GOMPHOCERATIDÆ:—Aperture contracted. Gomphoceras (including Hall's Orthoceras fusiforme;) Phragmoceras; Oncoceras;: Lituites?

2. HETEROSIPHONIDE:--Aperture unknown, perhaps contracted: Siphuncle more or less complicated, or otherwise marginal, with conical orthoceras-like shell. Septa simple or slightly wavy. (See remarks below.) Endoceras; Cameroceras?; Gonioceras; Ormoceras; Ascoceras.

3. NAUTILIDÆ: Aperture open. Septa simple, Siphuncle central or sub-central: Orthoceras; Nautilus; Lituites; Hortolus; Aploceras (including Hall's Cyrtoceras Annulatum?) Nautiloceras; Trochoceras.

4. TROCHOLITIDÆ:—Aperture open, Septa simple. Siphuncleinternal or "ventral." Trocholites.

5. CYRTOCERATIDE :- Aperture open. Septa simple. Siphuncle external or "dorsal" :- Cyrtoceras; Gyroceras; Cryptoceras.

6. CLYMENIDÆ:-Aperture open. Septa lobed. Siphuncle internal. Clymenia; Sub-clymenia.

VOL. II.---S

<sup>\*</sup> Many palecontologists will, no doubt, think an extended sub-division of this kind very unnecessary, and prefer to group these forms in two, or at the most, in three families; but in adopting this plan, the characters of the respective families become ill-defined, and the appreciation of transition groups much weakened; whilst, at the same time, a necessity is occasioned for the creation of sub-families or tribes. A classification which does not shew upon its face a greater distinction between Goniatites, Ceratites, and Ammonites, than between the last named genus and Hamites or Baculites for example, assuredly has no claim to be considered a natural grouping. In the arrangement given in the text, the second family is merely a provisional one, rendered necessary by our still imperfect knowledge of its included forms.—E. J. C.

7. ATURIDÆ:—Aperture open. Septa lobed. Siphuncle internal or nearly so, and very large. *Aturia* (*Megasiphonia*)—a Tertiary form.

8. GONIATIDE :- Aperture open. Septa with angular lobes. Siphuncle external. Goniatites (Aganides ;) Bactrites.

9. CERATIDÆ:-Aperture open. Septa with denticulated lobes. Siphuncle external. Ceratites; Baculina.

10. AMMONITIDE :- Aperture open. Septa foliated. Siphuncle external. Ammonites; Crioceras; Scaphites; Ancyloceras; Toxoceras? Hamites; Ptycoceras; Baculites; Turrilites; Hellicoceras; Heteroceras.

Under the name of HETEROSIPHONIDE, we have separated from the NAUTILIDE, all of those more or less imperfectly known forms (commonly classed with Orthoceras) which possess a large complicated siphon, or in which with other related characters, the siphon is marginal. We are fully aware that many objections may be urged against this view, but until a true nautilus be discovered with the peculiar character of siphuncle exhibited by Ormoceras for example, we feel justified in holding to the separation of this latter form, with Endoceras, &c., from the normal Orthoceratites. The external ridges on the siphuncle of Endoceras, although so distinctly pointed out by Hall, appear to be forgotten altogether in the descriptions of many Europeau palæontologists. Ormoceras, notwithstanding the central position of its siphuncle, is evidently closely related to Gonioceras; and through that genus, though less closely, to Endoceras.

If the separation of the Goniatites and Ceratites from the  $A_{MMONITIDE}$  be disapproved of, they may be placed in that family as separate tribes. Our present object, however, is not to discuss the classification of the chambered cephalopods, but to point out the occurrence in our Silurian rocks of a type hitherto unannounced below the Devonian formation.

In the fifth of the above families, that of the CYRTOCERATIDE, characterised by the presence of simple septa with external or socalled "dorsal" siphuncle, we have three genera: Cyrtoceras, a simply "horned" form, exceedingly abundant; Gyroceras, a discoidal or "rolled-up" cyrtoceras, but without contiguous volutions; and Cryptoceras, likewise a discoidal form, but with contiguous whorls. Of the last named genus, founded by D'ORBIGNY, but two species appear to have been hitherto recognised: the C. subtuberculatus (Nautilus subtuberculatus) from the Devonian beds of Nassau; and the C. dorsalis (Nautilus dorsalis Phil.) from the carboniferous limestone of Yorkshire. Quite recently, however, in a specimen from the Black River limestone of Lorette in Eastern Canada, submitted to us by Mr. Head of the Canadian Institute, we have remarked the cryptoceras type of structure, viz : simple septa and an unmistakably "dorsal" siphuncle, combined with a nautiloidal form of shell. Hall, in the first volume of his "Palzontology of the State of New York" figures and describes under the name of Lituites undatus a fossil that may perhaps be identical with the one now under review : but if so, the generic term " Lituites" should certainly give place to that of "Cryptoceras." The siphuncle is said to be dorsal: and Professor Hall describes the only examples known to him.as occurring in the Black River limestone of Watertown, in Jefferson County. This same Lituites undatus, is quoted by D'Orbigny in his "Prodrome" and also by, Pictet in the last edition of his "Traité de Paléontologie ;" but these paleontologists appear to ignore completely the dorsal position of the siphuncle as described by Hall. D'Orbigny indeed, places it immediately under the following generic definition "LITUITES. Breynius : coquille spirale, à tours contigus, siphon central;" and this central position of the siphuncle as an essential characteristic of *Lituites*, is also recognized by McCoy in his recent work on the British Palæozoic Fossils of the Cambridge Museum, as well as by all modern palæontologists. One thing therefore is certain. that whether or not our specimen be identical with that of Professor Hall, it has evidently no claims to be considered a Lituites. In the present note, however, we are unable to do more than announce the occurrence of the genus Cryptoceras in our Canadian rocks : the characters of the solitary specimen before us being too imperfect to warrant the bestowal of a specific name.

\*\*\* Since the above was written, we have learned that several examples of this fossil type, under the name of *Lituites undatus*, have been obtained by the Geological Survey of Canada from the Black River limestone of Lorette. It is very probable that many of the Silurian "Lituites" will prove when more closely examined, to belong to Cryptoceras, or to Barrande's new genus, Nothoceras: a notice of which (Bulletin de la Société Géol. de France, T. XII. p. 380,) has only just reached us. Although stated to have been read before the Society on the third of March, 1856, the Bulletin containing the notice was not issued until March in the present year.

### ON SIR DAVID BREWSTER'S SUPPOSED

In Nothoceras, the bent edges of the Septa (the *goulot* of the French palæontologists) protecting the Siphuncle, instead of being deflected backwards as in Nautilus, Cyrtoceras, &c., are deflected forwards, or towards the opening of the shell, as in the Ammonites.

# ON SIR DAVID BREWSTER'S SUPPOSED LAW OF VISIBLE DIRECTION.

BY THE REV. GEORGE PAXTON YOUNG, M. A., PROFESSOR OF LOGIC AND METAPHYSICS, KNOX'S COLLEGE, TORONTO.

Read before the Canadian Institute, March 7th, 1857.

Sir David Brewster claims to have proved experimentally, that, in monocular vision, whatever be the direction in which a ray strikes the retina, it gives the sensation of vision in a direction perpendicular to the retina at the point of excitement. This is his Law of Visible Direction. A careful examination of the eye has shewn that the retina and the cornea have a common centre (which may, therefore, be conveniently termed the centre of the eye), and that a normal to the retina at the point where the picture of a small visible object is formed, almost exactly coincides (at least in pencils of moderate inclination to the axis of the eye) with the line joining the centre of the eye and the object; so that according to the Lawof Visible Direction. a small object is seen in the direction (nearly) of a line drawn from it to the centre of the eye. From this law of visible direction in monocular vision, has been derived a corresponding Law of Visible Position in binocular vision; which is, that a small object seen with both eyes, appears at the point where the lines of visible direction for the two eyes meet; the meeting of these lines being a condition indispensable in order that the object may be seen single.

These laws, while admitted by some philosophers of high authority, have been called in question by others, though I have never seen any thing like a satisfactory refutation of the arguments advanced by Sir David Brewster in support of his theory. I agree with those who deny that Sir David's reasoning is valid; and I propose in the present communication to shew that the experiments on which he relies are quite inconclusive; in doing which, it will be sufficient to discuss the case of monocular vision; for, since the law of visible position in binocular vision is professedly derived from that of visible direction in monocular vision, it follows that if the latter be destitute of evidence, the former must be given up likewise.

Sir David Brewster has no where formally explained what he means by visible direction; at least he has not done this in those papers in the Philosophical Magazine, which are expressly devoted to the proof and illustration of his Law; in consequence of which, the real import of the Law is involved in considerable doubt. But probably Sir David would accept the following as a true statement of what he holds, viz : that the mind, being mysteriously united with the retina as part of the living organism of the body, is immediately cognizant of the affections excited in the retina ; and that it refers the affections of which it is thus cognizant to a stimulus situated in the direction of a normal to the retinal surface. A writer in the Athenaum for February 7th, of the present year, thus states what he supposes to be Sir David's theory : "The mind, residing as it were in every point of " the retina, refers the impression made upon it to a direction coin-" ciding with the last portion of the ray that conveys the impression." This is undoubtedly a mistake. Instead of : refers the impression to' a direction coinciding with the last portion of the ray that conveys the the impression, the statement should have at least been : refers the impression to a direction perpendicular to the retina at the point where the refracted ray falls upon its surface. With this alteration, the sentence quoted would substantially agree with what I have expressed. Now it is important to observe at the outset, that, even if it be true that the mind "residing as it were in every point of the retina," or, to use a less objectionable mode of expression, mysteriously united with the retina as part of the living organism of the body, is immediately cognizant of the retinal affections, this is a metaphysical truth, which does not admit of being experimentally demonstrated. It must be established by its proper evidence: and this is of itself enough to shew that Sir David Brewster, in fancying that he has experimentally proved his law of visible direction, must be labouring under some delusion. From the nature of the case, physical experiments are inadequate to establish a law whose necessary basis is a metaphysical principle.

Passing this, however, let us proceed to examine Sir David Brewster's experiments The following is perhaps the most beautiful and plausible of the *direct* experiments on which he relies in support of his Law: "Having expanded the pupil by belladonna, look directly "at a point in the axis of the eye. Its image will be formed by a

" cone of rays variously inclined from 85° to 90° to the surface of " the retina. While the point is distinctly seen, intercept all these " different rays in succession, and it will be found that each ray gives " vision in the same direction, the visible point retaining its position. " Hence it follows, that on the part of the retina in the axis of vision. " all rays, however obliquely incident, give the same visible direction " perpendicular to the surface of the membrane." Now, I admit that a very interesting fact in vision is here proved : and let Sir David Brewster have the credit of having established it. But what is the fact proved ? It is, that all rays falling upon the part of the retina which lies in the axis of vision, give rise to the same subjective affections, whatever be the inclination at which they impinge upon the retina. Nothing else than this is made out. Sir David Brewster indeed thinks, that, because the visible point retains its position while the different rays in succession are intercepted, we are warranted in affirming that "each ray gives visible position in the same direction." But what is meant by the visible point retaining its position? There does not exist any visible point, or image, to which position in absolute space, apart from the mind, can be ascribed. When a visible point, therefore, is said (popularly) to retain its position, the idea really intended to be conveyed, must be, that no appreciable alteration is experienced in the subjective affections of which we are conscious. If we refer (as we are under no necessity of doing) our subjective affections to a remote stimulus, it is of course to be expected, that, while no appreciable change takes place in the subjective affections, no wavering or variation shall occur in the estimate which the mind forms of the direction of the stimulus. But the circumstance of "the visible point retaining its position" indicates nothing whatever regarding such reference, whether determinate or variable. A visible point is a subjective phenomenon. A change in its position is a change occurring in a subjective sphere. The absence of any change in its position is the absence of (appreciable) change, in a certain respect, in our subjective affections. The experiment described merely shews, therefore, that all rays falling upon the part of the retina in the axis of vision give rise to the same subjective affections; and hence it has no weight in demonstrating the law in support of which it is adduced.

But besides failing to observe that the circumstance of the visible point retaining its position while the different rays in succession are intercepted, amounts to no more than this, that rays incident upon the same part of the retina at different obliquities give rise to

the same subjective affections, Sir David Brewster has committed the glaring impropriety of assuming that an object in the axis of vision is seen in the direction of the axis. For how does he argue ? " Each ray gives vision in the same direction, the visible point retain-"ing its position." Let this sentence pass, dubious as it is; and what next? "It follows, that, on the part of the retina in the axis " of vision, all rays, however obliquely incident, give the same " visible direction, perpendicular to the surface of the membrane." Indeed ! How does this follow ? Grant that the rays in question all give the same visible direction (though the only thing proved, is, that they give rise to the same subjective affection); how does the idea of a direction perpendicular to the surface of the membrane creep in? The cone of light through which vision is produced, contains a line of rays, no doubt, which fall perpendicularly upon the eye, and pass to the retina without refraction; and it may be fancied that these at least "give visible direction" in the axis of vision. But how can such a thing be proved? How does it appear, that, when rays come to the eye along the axis of vision, the mind determinately refers the subjective affections occasioned by such rays to a remote stimulus, situated somewhere in the axis? Let E represent the eye, and O an object towards which the axis of the eye is turned. It may perhaps be said, that, if you ask the observer, he will tell you that he refers, and cannot help referring, his sensation to a stimulus in the line E O. But he means nothing more by this, than that he is unable, while his eve is turned towards O, to alter the character of the perception realized. That nothing more than this can be intended, and that there is not, in truth, any intuitive or instinctive reference to the direction E O, is rendered certain by a consideration which shall afterwards be more fully brought out, viz: that the object O is not an object of intuitive knowledge at all. Distant objects can only be known mediately or inferentially. And if the object O be not immediately known even as existing, it follows, a fortiori, that the direction E O is not immediately known ; so that an instinctive, intuitive or immediate reference of a visual impression to the direction E O, is an absurdity.

This may suffice, as regards *direct* demonstration. *Ex uno disce* omnes. No direct demonstration can possibly indicate any thing else than the similarity or dis-similarity (as the case may be) of the subjective affections produced by rays impinging upon particular parts of the retina. Let us proceed to consider next whether Sir David receives any more effectual support for his doctrine from the *indirect* 

method of proof—the method which, beginning with a certain hypothesis, and deducing the results to which it leads, concludes from the harmony between these results and actual fact, that the hypothesis is correct. And here again, as I intend to limit myself to a single example, I shall choose the most elegant and specious that I can find.

Many writers on vision have perplexed themselves with the enquiry : why are objects seen erect, when their pictures on the retina are inverted ? Sir David Brewster tells us that this is a necessary consequence, and therefore a confirmation, of his Law of Visible Direction. "The phenomenon," he writes, "of an erect object from an "inverted picture on the retina, which has so unnecessarily perplexed "metaphysicians and physiologists, is a demonstrable corollary from "the law of visible direction for points. The only difficulty," he adds, "which I have ever experienced in studying this subject, is, "to discover where any difficulty lay."

In examining this statement, I would repeat the remark previously made, that the image or "phenomenon" of an object has no existence in absolute space, apart from the mind. No doubt, the language familiarly employed in treatises on vision tends to suggest a contrary idea to careless and unreflective readers; and few philosophers are at less pains to avoid phraseology liable to be misunderstood, than Sir David Brewster himself. He not only at one time, tells us of an image being formed in front of a wall, or behind a wall, according to the circumstances of the experiment ; and, at another time, speaks of images floating in the air at a distance of so many feet from the eye; but he even accuses certain images of assuming a position in space different from "their right position " But, of course, such languagewhatever be its meaning-cannot signify that images do ever actually exist in space, apart from the mind. I do not affirm that images are purely subjective states : modes of the ego considered per se, and out of all relation to matter : modes in which the ego might have existed, though matter had never been. Most metaphysicians take this view. A different opinion, however, may be maintained. It may be held that an image is not a purely subjective state, but is constituted by the mind's immediate apprehension of the non-eqo; that it is a product of two factors, the mental and the material, mysteriously united with, or existing in relation to, one another. Being desirous to avoid metaphysical discussion as far as possible, I shall not attempt here to judge betwixt these two opposite theories. But, whether the one or the other be correct; whether an image be purely subjective, or partake partly of the subjective and partly of the objective; this

at least is certain, that it is subjective in such a sense that it has no existence in absolute space, apart from the mind.

This explanation being made, we are now able to estimate aright Sir David Brewster's reasoning. Suppose rays from an object X Y to fall upon the retinal surface y x; the rays from X being brought to a focus at x: and those from y being brought to a focus at y. Sir David argues, that, according to his law, an impulse on the retina at x gives vision in a direction perpendicular to the retina at x; and that an impulse on the retina at y gives vision in a direction perpendicular to the retina at y; and that, therefore, the phenomenon of an erect object is produced, though the picture on the retina is an inverted one. But " the phenomenon of an erect object," it must be kept in view, is not any thing having existence in space apart from the mind, and standing in an erect posture. It is a subjective (I do not say, purely subjective) representation. Now I presume that Sir David Brewster does not wish us to believe that this subjective representation itself is a corollary from the law of visible direction. He cannot mean more than that the mind's instinctive and determinate reference of the affections of which it is conscious to an erect exterior stimulus, is a corollary from the law of visible direction. And undoubtedly this reference is a demonstrable corollary from the law. But is it not plain, that, to assume that there is such a reference, instinctive and determinate, involved in, or connected with, the phenomenon of an erect object, is to assume the very thing about which there is any controversy ? For what is it which those demand, who ask proof of the law of visible direction? They demand proof of the assertion, that the mind instinctively refers its visual affections to a remote stimulus lying in any determinate direction whatever from the point of the retina excited.

Should the above criticisms be well founded, they are applicable to the whole of Sir David Brewster's reasoning; so that it is unnecessary to examine the details of other experiments to which he appeals. Our conclusion, therefore, is, that both his direct and his indirect proofs are entirely destitute of weight. The sole fact which he has established, is, that the subjective affections to which rays impinging on the retina give rise, are the same, whatever be the obliquity at which the rays strike the retina.

It is a curious circumstance that Sir David Brewster was anticipated in his Law of Visible Direction by a conjecture of D'Alembert, founded upon the idea that the stimulus proximately affecting the retina, acts, conformably to ordinary mechanical principles, in a

direction peppendicular to the retinal surface. "The celebrated D'Alembert," Sir David himself writes, in an article published in the Philosophical Magazine for May, 1844, "maintains that the action of " light upon the retina is conformable to the laws of mechanics; " and he adds that it is difficult to conceive how an object could be "seen in any other direction than that of a line perpendicular "to the curvature of the retina at the point of excitement."-The opinion here expressed was abandoned by D'Alembert in consequence of conclusions to which he was led from the erroneous data with which he was furnished as to the structure of the eye; but, as the consideration which seemed to him to give an a priori likelihood to a law of visible direction identical with that which Sir David Brewster supposes himself to have experimentally established, may perhaps be thought by some to possess a measure of weight, I would observe that neither D'Alembert's conjecture, nor the inference which he drew from it, is in the least degree warrantable. On the one hand, it is by no means to be admitted that the action of light upon the living nerve, where the objective and subjective meet together, must, as a matter of course, take place according to the ordinary mechanical laws that prevail within a strictly objective sphere. And, on the other hand, even were that allowed, it would furnish no presumption in favour of the idea that we see objects in a direction pependicular to the surface of the retina at the point of excitement. For who does not perceive that the question as to the direction to which the mind refers the stimulus that produces vision remains entirely undetermined, whatever be the conclusion we adopt as to the direction in which the retina is impressed ?

Not only has Sir David Brewster failed in proving his law of visible direction, but it may without difficulty be shewn that the mind does not instinctively refer its visual affections to a remote stimulus lying in any determinate direction whatever from the point of the retina excited, so that no definite Law of Visible Direction exists. This view, and also the ground on which it rests, were hinted at in a previous part of the paper; but it may be proper to bring it out more fully. It is based on the elementary metaphysical distinction between immediate and mediate knowledge : immediate knowledge being realised, when a thing is known in itself; and mediate, when a thing is known inferentially, through means of something else. Now, when the mind refers an affection of which it is immediately cognizant, to a remote stimulus, the judgment of the mind assigning a perpendicular direction or position to the stimulus, is mediate. No immediate,

intuitive knowledge of the position of any remote stimulus is realised : we only infer its position from the particular consciousness of which the mind is the subject. Suppose, for instance, that the eves are directed to a small luminous object at a little distance. A remote stimulus is not intuitively known even to exist. Dr. Reid, indeed, the founder of the Scottish School of Philosophy, taught that distant objects are immediately perceived : but this doctrine will no longer find a single intelligent defender. As Sir William Hamilton has pointed out, Reid here fell into a fatal inconsistency. Those metaphysicians who believe that material objects have an existence at all, apart from the mind, are now unanimous in admitting that distant material objects. like the luminous point referred to, are not immediately perceived; and I presume that Sir David Brewster would himself subscribe to this view, when formally presented to him. This leads at once to the result, that the visible position of a distant object is indefinite; for, the estimate which we form of the position, or of any of the relations, of a thing not immediately known, is liable to variation. Different persons, and even the same person at different times, may form extremely different estimates of the position of a point. But if visible direction be thus indefinite, it cannot be capable of being expressed by a definite law, either that of Sir David Brewster, or any other.

It might be thought, indeed, from a superficial view of the subject, that, in opposition to what has been said, impressions made upon the retina are determinately referred to particular directions. Is not every one, it may be asked, familiar with the fact that objects often appear where the observer knows them not to be, and where, nevertheless, he cannot help fancying them to be ? An object is known to be at A. The sense of touch assures us that it is so. Yet it appears to be at B. We are obliged, in spite of ourselves, to refer the visual impression to a stimulus in the position B, though our reason is satisfied that such reference is erroneous. No effort, as Sir David Brewster says, in describing a case of the kind, is sufficient "to dispel the illusion." Does not this prove that impressions made upon the retina are instinctively referred to particular definite directions? I answer: no. Take the simplest of all examples. To an observer looking at an object reflected from a plane mirror, the image appears (to speak popularly) behind the mirror. Now here undoubtedly a determinate effect is produced; an effect which no knowledge possessed by the observer, nor any effort of his will, can modify. But what is this determinate effect ? It is the image formed ;

and (as was previously pointed out) an image is a subjective phenomenon - not, perhaps, purely so, but subjective at least in this sense, that it has no existence in space, apart from the mind. In granting, however, that the observer cannot by any effort modify the image, or subjective phenomenon, connected with a particular impression made upon the retina-which is just granting, in other words, that he cannot make his perception any thing else than it is-we by no means grant that experience does not enable him to modify his reference of the visual impression to a remote stimulus. A child, or a savage, who had never seen a mirror before, would naturally refer the sensation of which he was the subject, to the influence of an object actually existing behind the mirror: but when a very little knowledge was obtained, such reference would no longer be made. And here let me remark that it is not true that, in matters of vision, we ever labour under illusions which refuse to be dispelled. When a child or savage sees an object reflected from a mirror, and concludes that the remote stimulus of vision is behind the mirror, two things must be distinguished: first, the image formed, in other words, the subjective phenomenon produced, or the consciousness realized; and secondly, the inference drawn, viz : that an object exists behind the mirror .--As far as the former of these is concerned, there is no illusion. The image is apprehended as it really is. To deny this, would be to say that a perception might be what it is not. In the latter point-the inference drawn-there is certainly room for mistake or illusion : but the erroneous inferences of an uninstructed observer are capable of being corrected.

I shall only add, that, should the views advanced in this paper prove to be well founded, they must materially affect the conclusions at which we arrive on some questions which have recently excited considerable discussion. I refer to the principles involved in the construction of the Stereoscope; to our (so-called) perception of relief; to the curious changes which often seem to take place in the solids represented by plane outline figures; and to other matters of like description, into the particular discussion of which it would be beyond our present purpose to enter.

## NEW TRAVERSING STAGE FOR THE MICROSCOPE.

BY PATRICK FREELAND,

REGISTRAR, TORONTO UNIVERSITY.

Read before the Canadian Institute, 21st February, 1857.

The high position now occupied by the microscope, both as an instrument of scientific research and as a means of obtaining useful recreation, as well as the great attention given to it, in order to bring it as near as possible to perfection, render unnecessary any apology from me in bringing under the notice of the Canadian Institute what I conceive to be an improvement in the construction of the stage, or the apparatus used for holding the object while under examination, and for moving it about so as to bring at pleasure any portion of it into the centre of the field of view. The importance of being able to move the stage plate of the microscope in every direction easily and with precision, is well known to every microscopist, and many methods of doing so, each having its own peculiar merits or defects, have been adopted.

In 1831, Mr. Cornelius Varley constructed the first microscope with a lever stage movement, for which he subsequently received the gold Isis medal, awarded to him by the Society of Arts of London .-But the application of the lever in Mr. Varley's microscope was soon found to be objectionable, its fulcrum was attached to the stage itself, and the lever projected downwards under it. thusremoving the hand to a considerable distance from the focus adjustment, while the whole arrangement was complicated. It was however, subsequently much improved by Mr. Alfred White, who simplified very much the whole stage movement, and entirely dispensed with a great deal of what encumbered Mr. Varley's. Instead of having it below the stage, Mr. White brought the lever above, and placed its fulcrum on a stout arm projecting from the upright which carried the compound body; and in this form the lever stage is still mostly used-this stage is described by Mr. White in the first volume of the Transactions of the Microscopical Society. It consists like almost all traversing stages, of three plates of brass laid one above the other, the lowest one being fixed and the other two provided with dovetailed guides and slides, so that each may be

277

easily moved by the lever either in the same or in parallel planes, but at right angles to each other; while if both be moved at the same time, a diagonal motion is obtained at the pleasure of the operator.

This plan of a traversing stage has many advantages, it is in the first place simple in its construction, and is very easily managed and as the end of the lever to which the hand is applied moves in all cases in exactly the opposite direction to that in which the stage is moved by it; and as the compound microscope always inverts the image of the object under examination, the object will appear to move in the direction of the hand. But the great objections to this form of the traversing stage, are that the lever is very much in the way, and being attached to one of the extreme angles of the stage, when, it is in use, the strain is thrown more upon those parts of the stage in the vicinity of the lever, which wear away more rapidly than the others, and soon impair the correct working of the instrument.

The next mode of producing a traversing motion, is that usually known as Turrell's plan, and is described by that gentleman in the 49th volume of the transactions of the Society of Arts. In this mode the lever is entirely dispensed with, and the different motions are communicated to the stage plate, by two milled heads placed together, at the right hand side of the stage, and turning upon concentric axes. The motion of one of the plates of the stage is produced by turning one of the milled heads attracted to a pinion which works in a rack attached to the under side of the plate. The motion of the other plate is produced by the other milled head which works a screw, in a thread attached to the under side of the second plate ; and by working the two milled heads at the same time, a diagonal motion is given to the stage. But apart from the complexity of this arrangement and its great liability to get out of order, it has several very serious defects, the greatest one being that in order to produce a diagonal motion in some directions it is necessary to use both hands, an objection which this form of stage was expressly designed to meet, but which it only partially removes.

In the microscope which I have now the honor to bring under the notice of the Canadian Institute, this difficulty is entirely overcome, and by a combination of the lever and the screw, the advantages, without the defects, of both Mr. White's and Mr. Turrell's plans are secured.

I have placed immediately under, and running the whole way across the stage, the lever f g Fig. 1. on which for about two inches

of its length, at an equal distance from either end of it, is cut a spiral groove, h *i*. The fulcrum is at f on the left side of the stage in **a** small pillar rising out of a slight projection from the lowest plate of it, and is so contrived, that the lever can be easily turned on its own axis. On the other end of this lever at q a milled

head is fixed, by which the different motions are given to the lever. An enlarged representation of the adjustment for the fulcrum is given at Fig. 2., representing a small brass pillar, which passing through the under plate of the stage, is held down by a forked piece of brass screwed to the under side of the plate, and accurately fitting the neck cut in the pillar at o, so that the pillar can readily be turned on its own axis while firmly held in its place. The end of the lever having a similar neck, is shown at m; this fits into the pillar and is held in its place by a small forked piece of iron, n. passing down over the neck, and secured by the small screw p. The grooved part of the lever passes through a short brass tube, e (Fig. 1.,) (an enlarged

representation of which is given at Fig. 3.) to this tube a small stem r is attached, which screws into the under side of the upper stage plate by a left handed screw, a small steel screw s passes through the tube, the point of which fits into the spiral groove

h i of the lever. The upper stage plate slides in dove-tailed grooves made in a frame of brass, and this frame slides in the dove-tailed grooves at a b and d c but at right angles to the former. The arm which carries the compound body rises from the projection shown at k; by turning the milled head g the action of the spiral groove on the pin in the tube e moves it, and with it the stage to which it is attached, to or from the hand; while by moving the milled head backward or forward, a transverse motion is produced, and by combining the two, a diagonal movement at the will of the operator is secured.

The advantages of this plan are simply these: 1st, the lever is not in the way of the operator, yet very easy of access, and the power is applied as near the centre of the stage plate as it is possible for it to be. 2nd, only one hand can in any case be necessary to produce every motion that may be desired; and 3rd, it is very simple, is not liable to get out of order, and if it should happen to get out of repair can readily be set right again.

I may perhaps be permitted to point out another improvement in this instrument, which has lately been introduced in England, and I believe also in the United States. This consists of a new arrangement for the coarse adjustment of focus.

The rack and pinion movement which is always unsteady and works by jerks even when most carefully constructed, is here dispensed with, and instead of it a chain movement is substituted, which has the advantage of being much smoother, and more sensitive, of being less likely to become unequal by wear, and of being easily tightened if it should cease to act, or "loose time" as it is technically called, while its delicacy and smoothness admit of an exact adjustment being made by its means alone, even when using high powers.

### REVIEWS.

Gales in the Atlantic: By Lieutenant Maury, U. S. N., Washington Observatory, May, 1857.

In extending a knowledge of the physical phenomena of the Atlantic Ocean, the publications of the Washington Observatory under the able superintendence of the author of the "Physical Geography of the Sea," stand deservedly pre-eminent. Lieutenant Maury's Wind and Current Charts—an annual volume of over nine hundred quarto pages accompanied by a large number of ingenious and elaborately executed maps—are universally allowed to have contributed the most essential aid to navigation. As Humboldt truly states, the shortening of many a dreary voyage may be cited as one of their results. In that valuable publication, the gales of the Atlantic are especially discussed; and various explanatory

280

diagrams are given in illustration of their peculiarities of occurrence. In the publication now under notice, this subject is still further elaborated; and we are presented with a chart of the North and South Atlantic Oceans, for each month of the year, shewing by an ingenious arrangement of colours, the comparative frequency of gales, over given areas, in the different months. Three facts are brought strikingly before us by an inspection of these gale-charts. First, the marked preponderance of stormy weather generally in the North, as contrasted with the South Atlantic, at least for the winter months; secondly, the scarcity of gales between the parallels of 30° north and south; and thirdly, the remarkable difference between the frequency of gales in the winter, as compared with the summer months, over that region of the North Atlantic lying more especially in the track of ocean travel between the United States and Europe. Whilst in the October, November, December, January, February, March, and April charts, an extended and unbroken line of colour stretches from the British Isles to the Atlantic sea-board of the States only varying somewhat in intensity and breadth-in the June, July, and August charts, merely a few limited patches meet the eye. In his brief explanation of these charts, Lieutenant Maury states that they were principally worked out with a view to ascertain the most tranquil and favorable time for laying the sub-Atlantic telegraph. This time, and necessarily also the most favorable season for passenger travel across the Atlantic, he shews to be about the end of July. or the beginning of August. "At no season of the year," writes Lieutenant Maury, " can the passage around either of the 'Stormy Capes,' as poets call them, vie for storms with the winter passage. between England and America." And again, "this part of the ocean is most tranquil in summer. Taking averages, we have in it fewer gales but more fogs and ice in June than in July or August : but fewer fogs and least ice in August. The last of July and first of August appears to be the most favorable time for laying the sub-Atlantic telegraph. This information may be useful to invalids and others crossing the Atlantic, as well as to those engaged in this enterprize."

Although these gale-charts are intended to be considered in the light of approximations merely, some idea may be formed of the care bestowed on their compilation, when we state that they embody the results of no less than 265,292 days of observations.

E. J. C.

## 282 REVIEWS-JOURNAL OF EDUCATION, MONTREAL.

Journal de l'Instruction Publique : Montreal, (Bas-Canada,) 1857.--Nos. 1, 2, 3 and 4.

Journal of Education: Montreal, (Lower Canada,) 1857. Nos. 1, 2, and 3.

We notice with great satisfaction the nearly simultaneous appearance of the two educational journals of Lower Canada: each, as we trust, and fully believe, the *avant courier* of a new era for educational progress in that part of the Province. They appear as the organs of the improved Common School system of Lower Canada, now established with its twin Normal Schools at Montreal, the McGill and the Jacques Cartier Schools; and at Quebec the Laval Normal School; all under the efficient control of the Hon. Pierre J O. Chauveau, Chief Superintendent of Education for that part of the United Province.

It argues well for the success of the newly inaugurated system that an honest attempt is thus being made to adapt the educational system, not only to the wants, but also to the opinions and prejudices of the two very diverse elements which constitute the combined population of that portion of British North America, instead of attempting any forced and unattainable theoretic uniformity. The two journals thus addressed to different sections of the population. who are being trained under systems diverse in some important respects, and with different languages, historical associations, and aims: are designed each with a view to their own special readers; while, nevertheless, they have much ground in common, and cannot fail to exercise a beneficial and stimulating influence on each other. That they are to move in harmonious combination is the present purpose of their editors, and in this worthy aim we wish them all success. The editor of the English journal, after detailing the design and objects of the work, and stating the varied contents with which it is purposed to fill its pages, thus concludes his first leading article, speaking in part for both journals:

Every thing congenial with public instruction will find its place in our columns, varied we hope in the most pleasing manner. Poetry will now and then lend us its harmonious accents. Science in its innumerable departments will afford us amusement and instruction. History, and more especially that of Canada, will frequently unfold an interesting page to our young readers. The passing events of our day, without any allusion to local polities will teach us many a lesson, and finally R sligion that aromat (as a great English chancellor had it,) without which all science would be putrified, religion we hope will pervade all our writings, and by its sacred influence will exclude from our columns anything that might offend the eye even of the most scrupulous of our readers. With the help of these powerful elements, and we hope, with the assistance of all the friends of education, "Le Journal de l'Instruction Publique," and the "Lower Canada Journal of Education." will be enabled to accomplish the all important mission confided to them.

That mission, difficult in any country, is rendored more so in ours, by the complications which difference of language, origin and creed, bring with them in every public undertaking. These, however, we hope not only to surmount, but we are sanguine enough to see in them if properly attended to, new elements of success. Amidst the furious struggles of the political world, all sections of the population require a neutral ground where they can meet for one common object, with one common accord. This can no where be found but in education, in science, and in literature, and presents little difficulty with us in Lower Canada, from the fact, that through mutual for bearance, education has never been the cause of either political or religious dissension.

It will be one of our chief objects to make each section of the population better known to the other, and to spread useful information through the means of each of these journals, on the educational progress not only of its own class of readers but equally of those of the other. Having at our disposal a large supply of English and of French newspapers and periodicals, as well from the old world as from our own continent, we shall be enabled, with the aid of appropriate translations to offer to the readers of each of our papers, matter that is not generally within their reach. We will endeavour from these sources to diversify the columns of both publications and render them entertaining to all; and we may add, that to our knowledge, a great number of families who are acquainted with the two languages will become subscribers to both. This fact will of course increase our responsibility and stimulate our exertions in relation to each of the two journals.

Under two different names, clothed in two different languages, but both harbingers of peace, both advocates of the same cause, we send forth these two papers, and with care, with fondness, with anxiety alike for both, for both we ask—and to both, we trust the public will say—success.

To this desire we heartily respond. Education universally diffused among the people of Canada is an indispensable element to its true progress; and the rapid advances we are now making in agricultural and commercial prosperity, render such not less, but more indispensable, if we would not sink into mere trading and labouring drudges with no higher ambition or nobler aim in life than that of Bunyan's "Man of this World," shown to Christiana and the boys in the "Significant Rooms" of the Interpreter's House. The quaint fancy of the glorious old Dreamer's parable is replete with lessons for all of us in these days and this land, where the one object of life so often seems the mere haste to get riches. "The Interpreter takes them apart, and leads them into a room where was a man that could look no way but downwards, with a muck-rake in his hand; there stood one also over his head with a celestial crown in his hand, and proffered him that crown for his muck-rake : but the man did neither look up nor regard, but rake to himself the straws, the small sticks, and dust of the floor."

Some such significance both the Educational Journals of Lower

Canada seek to set forth in the teaching they inaugurate. The "Celestial Crown" which he who is engrossed by the raking together of the world's dust and straws cannot discern, is not indeed mere intellectual culture, though that unquestionably has an elevating tendency. It raises men's thoughts, uplifts their aspirations, and precludes in some degree the all absorbing sovereignty of mammon's worship.

The motto of the English Journal is: "Labor vincit omnia," that of the French Journal : "Rendre le Peuple meilleur," but both exhibit their chosen cri de querre encircled by the Canadian emblems of the beaver and the maple-wreath; within which, and resting against the symbol of our common christian faith, is the open volume, inscribed : "religion, science, liberty, progress," as the means which-notwithstanding the differences separating those of English and French language and origin from each other,-they thus acknowledge to be, each and all of them, indispensable as the allies and coadjutors of national education, by which all difficulties must be overcome, and all obstacles removed which would hinder the making of the people better. That these, the true elements of a people's greatness and prosperity, may advance simultaneously as the fruits of the great blessing of a wise national education throughout every section of our Province, is, and must be the earnest desire of every one who believes that the " people are destroyed for lack of knowledge ;" but that "righteousness exalteth a nation, and sin is a reproach to any people."

We would gladly see both of these Journals obtain an extensive circulation in our upper section of the province. The more we learn to take an interest in all which pertains to the welfare of each other, the better will it be for our common country and the success of all in the progress of which we have a mutual advantage to reap, and we gladly cherish the belief that the common ground on which we can meet and exchange sympathy is neither narrow nor straightened. Views of the Jacques Cartier Normal School, illustrate the first number of the one Journal, and of the McGill Normal School the other. Already papers are introduced as the first of a series, on questions interesting to all engaged in education; while another series devoted to "the Colleges of Canada," begins with the history of Laval University, and with a view of the extensive but singularly unacademic looking range of buildings which furnish accomodation for that Institution at Quebec. This will be followed by similar notices of the other educational institutions of the Province, and is

not to be confined exclusively to Lower Canada. Incidents of early Canadian history are also introduced in a pleasing style, and addressed as these are in the *Journal de L'Instruction Publique* to those of French origin, they are presented in a form calculated to give piquancy and interest to us, who, when considering them at all, are apt to overlook some of the minuter points best calculated to awaken an interest in our historic past. Altogether we gladly welcome these Education Journals as most useful and acceptable additions to the periodical literature of the Province.

D. W.

Reid's Works, (Essays on the Human Mind, &c., ;) with selections from his unpublished letters; with a Preface, Notes, and Supplementary Dissertations, by Sir William Hamilton, Bart. Edinburgh: 1854.

The following article is not a *criticism*, but simply an *exposition* of the late Sir William Hamilton's doctrine of Sensitive Perception; and it is designed to supply what has hitherto been felt by many, and especially by those entering on the study of philosophy, to be a great desideratum : an accurate, and yet not very technical statement of the only consistent and plausible system of natural realism which is before the world. It is necessary to explain that the writer of the article considers Sir William's doctrine to be in several important respects erroneous. But without bringing forward the grounds of this opinion, he has limited bimself at present to the task of exposition. The only exceptions to this, are, the foot note on the subject of the extension of body, and the reference made in the note at page 295, to a former article in this journal, on Sir William Hamilton's doctrine of consciousness.

Under the general title of Sensitive Perception, Sir Wm. Hamilton includes sensation proper and perception proper; or more simply, without the addition of the epithet *proper*, sensation and perception.

Each of these forms of sensitive perception is held to be an act of the mind in which an object is known. Sensation is allowed indeed to be a lower exercise of intelligence than perception; because, as will afterwards appear, it is merely the knowledge of a fact, while perception is moreover the knowledge of a relation: but still both are acts of intelligence. The mind in sensation, as well as in perception, is cognizing an object. This is not the universally received doctrine of philosophers; for some have thought that sensations, as mental states, are capable of being distinguished from the acts of intelligence by which a knowledge of them is realised. In fact, it has been held, and by no mean authorities, that sensations may exist in the mind, without ever becoming known at all. But according to Hamilton such opinions are untenable. He denies that sense, either in its lower or in its higher form, can be discriminated from intelligence. "Quid erit sensus," he asks with Tertullian, "nisi ejus rei quæ sentitur intellectus ?"

Sensation is not only an act of knowledge, but more particularly, one of immediate knowledge or consciousness. As we shall have frequent occasion to use these expressions, immediate knowledge, and consciousness, it may be well to define them formally. An object is said to be known immediately, when it is apprehended in itself; in contradistinction to mediate knowledge, which takes place when an object is apprehended through something else. Thus. a blind man, made sensible through means of his staff, of an obstacle before him, knows the obstacle, but only through something else. This is mediate knowledge. On the other hand, how is one aware of the thought which at any moment exists in his mind? He apprehends it, not through anything else, but in itself. This is immediate knowledge. Consciousness is employed by Sir Wm. Hamilton, and will be used throughout this article, as synonimous with immediate knowledge. When therefore sensation is represented as an act of immediate knowledge or consciousness, the meaning is, that the object known in sensation is apprehended in itself, and not through the medium of aught else.

This leads to the enquiry, what is the object of which we are conscious in sensation? Sensation is an act of knowledge; it is an act of immediate knowledge: what is the thing immediately known?

In answer to this we remark that the living organism of the body is capable of having a great variety of affections excited in it, either by external or by intraorganic causes. In the well-known theory of Dr. Reid, such affections are recognised as the antecedents of our sensations. The sensation of sweetness, for example, is consequent upon one particular modification of the animated organism; the sensation of redness upon another; the sensation of the odour of a rose, upon a third; and so forth. The sensorial affections which are thus regarded by Reid as the antecedents of our sensations, constitute, according to Hamilton, the objects known in sensation. The living organism, in consequence of the application of some stimulus, is affected in a certain way; the mind immediately knows, or becomes

286

conscious of the organic affection; and it is in this immediate knowledge or consciousness that sensation consists. Sensation may accordingly be defined to be an act of consciousness whereby we apprehend in our body, certain special affections of which, as an aminated organism, it is contingently susceptible.

In saying that the object of which we are conscious in sensation is an affection of the animated corporeal organism, let it be understood that Hamilton does not altogether negative the commonly received opinion, that the object of sensation is in the mind. A word of explanation is requisite here. The body, as animated, ought not in propriety to be considered external to the mind; for it exists in a mysterious connection with the indivisible thinking principle, in consequence of which, the affections of the living organism are apprehended as subjective affections. The terms objective and subjective denote, the former what is without the mind, and the latter what is in the mind. Now undoubtedly, the body, as a material organism, with the general relations of extension under which it in that character necessarily exists, is without the mind, and can only be apprehended objectively; but as a living organism, it is in union with the mind, and its affections are felt as subjective. The general relations of extension under which our bodies exist as material substances, belong to our bodies alone. They cannot in any sense be predicated of the mind. I, the Ego, do not exist under any relations of extension. But the special affections excited in my body as an animated organism, I claim as mine. I am conscious of them as affections of Self. It is only with this seriously qualifying explanation that Sir W. Hamilton would subscribe to the doctrine of Reid, and of philosophers generally. that the object of sensation is in the mind. He would not allow that it is in the mind purely. Strictly, it is a sensorial affection, which we are constrained, however, to view as of the Ego, in consequence of the union subsisting between the Ego and the living organism.

In the opinion of Reid, the dependence of our sensations upon affections of the bodily organism is altogether arbitrary. A piece of sugar is taken into the mouth; the organ of taste is affected in some unknown way; thereupon the sensation of sweetness arises. So says Dr. Reid, and he tells us that no necessary connection exists between the condition determined in the organ, and the sensation to which it is antecedent. It is a connection which has been established arbitrarily, by the will of the Creator. Had the author of our being so pleased, the sensation of sweetness might have been made to arise, not in connection with the particular condition of the body upon which it is actually consequent, nor in connection with any state of the organism whatever, but as the consequent of some change in the planet Jupiter, or in the volcanoes of the Moon. But on the view taken by Sir W. Hamilton of the object of sensation, such an opinion is manifestly inadmissible. If sensation be, as he maintains, the immediate apprehension by intelligence of certain affections in our living bodies, the dependance of our sensations upon our organic states cannot be arbitrary. To speak of an act of consciousness without an object, would be a contradiction in terms.

Let us now turn to perception, the other form of sensitive apprehension. According to Sir W. Hamilton, perception is, like sensation, an act of immediate knowledge or consciousness; but whilst the latter has for its object, as we have seen, affections of the Ego, the former has for its object relations of the Non Ego. Is it asked : what are these relations, and how are they presented to the mind so as to be perceived? The answer is : they are relations of extension, and they are apprehended in and along with our organic affections. Here, for the sake of simplicity, as well as because the distinction requires to be made on other accounts, we shall consider separately the relations of our organism to itself, and the relations of the organism to what is extraorganic. In the first place, with regard to the relations of our organism to itself: suppose that affections locally out of or external to one another are excited in the organism by some stimulus. The mind immediately apprehends the fact of their existence; and this is what we call sensation. But in immediately apprehending affections mutually out of one another, it obtains a consciousness of the relation of mutual outness which they bear to one another; in other words, it becomes conscious of the organism as existing under relations of extension. This is perception, apprehending our body as a finite, extended-that is, as a material object.\* In the next place, with regard to the relations in space of the material organism to what is extraorganic, in order to show how these become objects of perception, we must refer to a class of sensorial affections which possess a character altogether peculiar; we mean modes of resistance. In

<sup>\*</sup>Sir William Hamilton defines Body to be *that which occupies space and is contained in space:* and (as the text explains) an objective reality answering to the definition is, according to him, ascertained to exist, in the consciousness which we have of affections of the corporeal organism mutually external to one another.

Now it is worthy of remark that the consciousness here described—and which is the only consciousness that is supposed to reveal the extension of matter—does *not* reveal matter or body as *continuously extended*. We offer no criticisim now on Sir W. Hamilton's general doctrine. For the sake of argument, let that general doctrine be admitted. Let it be admitted, in particular, that, when the mind perceives, it cognizes a plurality of organic affections in their relation of mutual outness to one another. Does it follow that the organism in which two such affections A and B are simultaneously apprehended is a *continuum*, a substance stretching with unbroken extension from the locus of the one affection to that of the

### DOCTRINE OF SENSITIVE PERCEPTION.

fact, resistance as a subjective mode will, upon reflection, be seen, (Sir W. Hamilton holds) to be a relative, having for its correlative (the consciousness of which is therefore necessarily involved in our consciousness of resistance as an organic mode) a degree of outward force or pressure opposed to our locomotive energy. A person exerting a muscular effort, and feeling that the limb which he essays to move is impeded, cannot be conscious of resistance in this phasis, as an effort of self, an organic mode, without at the same time being conscious of it in its other phasis, as a force which is not self-opposing the attempted movement of his organism. It may thus be understood how relations in space of the corporeal organism to what is extraorganic, as well as relations in space of the organism to itself, fall within the reach of the perceptive faculty. Modes of resistance are immediately apprehended in the organism, as actual phenomena; this is sensation. In and along with the immediate apprehension of the fact of their existence, comes a consciousness of the mutual relation of outness in which they stand to one another; this is perception, revealing the organism as extended. But still further, in the same indivisible act of consciousness, we apprehend our organism standing in the relation to something extraorganic, of being resisted by it; this is perception recognising the existence of extraorganic objects. We do not indeed immediately know that what resists our locomotive energy is body or matter : we only learn in course of time, mediately, through induction, to connect pressure with bodies. But even prior to induction, immediately, in and along with sensations of resistance, and the accompanying perception of relations of extension in our organism, we have a knowledge of a resisting extraorganic something-whether identical with matter, or in any way connected therewith, deponent (to wit consciousness) saith not.

We remarked when speaking of sensation, that, in virtue of the union betwixt the mind and the animated organism, the special affec-

other? By no means. Extension is not supposed to be apprehended in the consciousness of the affections A and B as actual phenomena; but only in the consciousness of their mutual outness. If, however, neither the affection A per se, nor the affection B per se, reveals the organism as extended, then all that is fairly implied in the mutual outness of A and B, is, that the organism is plural, compound, having the locus of one element here, and that of another there—which is a very different thing from saying that it is a continuously extended substance, or composed of elements which possess continuous extension. Even though the organism of our bodies were known to exist as a congeries of elements external to one another, it might still be the case that matter did not possess extension in the proper sense of the term; in other words, matter might not be a substance in which different points could be taken, such that the substance would stretch as an unbroken continuum from one f them to the rest.

tions of the latter which are apprehended in sensation, possess a subjective character. They are felt as affections of self. But when we consider the general relations of extension under which the organism is perceived to exist-relations under which, as body, it necessarily exists-it is plain that as respects these, it has no claim to be viewed as subjective. They do not belong to it as united with the thinking principle, and cannot in any sense be predicated of self. Hence the organism which in sensation is reckoned of the Ego, is in perception accounted Non-Ego. This will probably seem strange doctrine to those to whom it is presented for the first time. That the organism in one aspect, as animated, and the object of sensation, should be of the Ego, while in another, as material and the object of perception, it is ignominiously reduced to the rank of Non-Ego-that it should be at once within and without the mind-may, as Sir W. Hamilton confesses, "appear not a paradox merely but a contradiction." But upon any theory, the connection between soul and body is a deep mystery-" the mystery of mysteries ;" and should a particular doctrine be in other respects agreeable to the imitations of consciousness, Sir William Hamilton contends that it is not rendered unworthy of acceptance, merely by being paradoxical or even seemingly contradictory [real contradiction being always supposed to be avoided] where it touches upon a matter so obscure.

Sir William does not admit that distant objects-that is, such as are not in proximate relation to the organism-are perceived. We perceive our body (as a material organism), and also extraorganic objects (not known by consciousness to be material) directly pressing against the organism; but we perceive nothing else. And indeed a moment's reflection is sufficient to shew that no system in which perception is viewed as an immediate cognition, can, without palpable error, affirm the perception of distant objects; for such objects are not in presentation to the mind, which never sallies out beyond the organism : and the mind cannot immediately apprehend what is not in presentation to it. Here Dr. Reid is grieviously in fault. His philosophy knows nothing of any such limitation of the range of the perceptive faculty as that described. He claims for perception a capacity of reaching to distant objects; and classes himself, even ostentatiously, with "the vulgar" who think that they perceive ships and houses, and men, and women, and other external realities which lie confessedly beyond the sphere of proximate relation to their organism. But this is, of course, perfectly absurd, on the supposition that perception is, what Reid every where affirms it to be, an immediate cognition. A book lies upon the table; our eyes

are directed towards it. Do we perceive it? In the proper sense of the term, assuredly not—that is, if perception be an immediate cognition. The book is not in presentation to the mind; and therefore any knowledge of it to which we attain is of necessity got mediately, as the result of the immediate cognition of some other object or objects lying within the reach of consciousness. Sir W. Hamilton, by denying that distant objects are perceived, escapes the charge of suicidal inconsistency to which his predecessor is exposed. According to his doctrine, the sun is not perceived in the firmament; its presence there is only known mediately and inferentially. David did not perceive Goliah when he was in the act of slinging the stone at his forehead; he merely *guessed*, as our American neighbours would say, founding on some particular consciousness of which he was the subject, that the giant was before him.

It will be obvious from the statement made, that sensation is the condition sine qua non of perception. For what is perception? It is the immediate knowledge of relations under which the organism exists, to itself, or to something extraorganic. But these relations are apprehended only in and along with organic affections. Let no organic affections be cognized - in other words, let there be no sensation—and the organism is no longer known at all; a fortiori its relations remain unknown. Perception therefore implies sensation as its indispensible condition. Yet it must not be supposed that, as Reid affirms, the one precedes the other in time. A sensation (Reid tells us) is first experienced; and and thereupon a conception of the external object which was concerned in originating it, together with an irresistible belief of the existence of the object, are instinctively suggested to, or inspired in, the mind. The conception and belief, forming the constituent elements of the perception, are suggested to, or inspired in the mind, on occasion of the sensation; so that the perception is subsequent, by however brief a period, to the sensation. In opposition to this, it is a perfectly essential part of the doctrine of Sir W. Hamilton, that though sensation must, indeed, as a conditio sine qua non of perception, be antecedent to it in the order of nature, the two are inseparable in time. The relations of extension which we apprehend in our body, when we perceive, are apprehended not after, but in and along with organic affections. It hardly requires to be added, that Hamilton's principles are diametrically opposed to those statements also of Dr. Reid, which represent the connection between sensation and perception (like that imagined by Reid to subsist betwixt our organic states and our sensations,) as arbitrary, and which affirm that

had it so pleased God, external objects might have been perceived by us, independent of sensation altogether. The dependence of the knowledge of a relation upon the knowledge of the things correlated is so far from being arbitrary, that even Divine power could not work an impossibility of giving us the former save on condition of the latter.

It cannot have escaped the notice of our readers, that perception must, on the doctrine expounded, have for its condition, not only sensation, but a plurality of sensations, because the perception of our organism (which enters into all perceptive consciousness, even into that of the extra-organic world,) is the consciousness which we have of the mutual outness of organic affections locally external to one another, and therefore plural. These affections do not indeed constitute sensation, but sensation consists in the recognition of them; so that perception can take place only where sensation is recognising a plurality of objects. Sir W. Hamilton not only holds this, but maintains that sensation itself supposes plurality in the object or objects of its apprehension. Let us quote his own words : "The second," (that is, the second condition of sensitive perception, in either of its forms; attention having been named as the first,) "is " plurality, alteration, difference, on the part of the perceived object " or objects, and a recognition thereof on the part of the perceiving "subject." However technical a sound these words may have in uninitiated ears, (Sir William is partial to esoteric phraseology,) the thing meant may, without much difficulty, be understood. Were the organism of our body without affections capable of being discriminated as plural, it would in fact be devoid of affections altogether; for what are affections except alterations or differences? If, therefore, sensation be the recognition of affections in the organism, it follows that where there is no alteration or plurality, there can be no sensation: as Hobbes has pointedly expressed it, "sentire semper "idem, et non sentire, ad idem recidunt." But indeed it is not in sensitive perception alone, that alteration is held to be an indispensable condition, but in every other exercise of consciousness likewise; and this, it may be remarked, is a grand fundamental principle on which Sir W. Hamilton relies, in seeking to refute those theorists in the highest region of thought, who claim for man a knowledge of the Unconditioned. The Unconditioned, including the Infinite and the Absolute. does not exist under characters of plurality or difference, and therefore, (Sir William argues) cannot be apprehended by human consciousness. Without, however, attempting to soar to such sublime speculations at present, but keeping to the terra firma of our
proper theme, it is sufficient to observe that the philosopher whose views we are expounding, assumes it as an axiom, that there can be no sensation and of course no perception, except on condition of plurality—plurality in this besides other respects, that the organic affections apprehended in sensation be out of, or locally external to, one another.

We are now in a position to understand the manner in which scepticism regarding an external world is dealt with by Sir William Hamilton.

Strange as it may appear to "the vulgar," (we employ Dr. Reid's familiar expression in no disrespectful sense), that any person out of a lunatic asylum should call in question the reality of external objects, and hesitate to allow the existence of the friend whom he beholds, of the food which he tastes, or of the wall against which he knocks his head, Sir William Hamilton maintains, that on any other doctrine than one of immediate perception, such scepticism not only is natural, but becomes a logical necessity. It is a first principle in philosophy that nothing should be believed, except it be known, either immediately in consciousness, or mediately by inference from data which consciousness affords. The Cartesian spirit, which doubts whatever is not established-which relentlessly bars out of the mind the most universally received maxims, so long as they seek admittance in the guise of dogmas-whose stern decision regarding every propositon affirming what is not either immediately or mediately known, is, let it be rejected : this is the true philosophic temper, not at all deserving the censure that has so often been ridiculously passed upon it, but on the contrary worthy of the highest commendation. Let, then, a student endowed with this disposition. address himself to the subject of sensitive perception, starting with the idealistic view, that we possess an immediate knowledge only of what is in our minds. How shall he proceed ? Suppose that, sailing down the St. Lawrence, he is admiring the strange and beauteous spectacle of the Thousand Isles. The only thing of which he is presumed to be immediately cognizant is a mental affection, a peculiar sensation connected (the vulgar think) with the presence of certain islands. But does the vulgar opinion-he, as a philosopher, is necessitated to ask himself-rest upon a solid foundation? Are there really any islands in the case? How does he know that? Should it be suggested that the sensations excited in him must have a cause, the question will still occur, must the cause be an external one? Must it be material? May not his sensations arise from his own mental energy, unconsciously exerted ? May those subjective

representations which (even after the manner of the vulgar) he is prone to ascribe to the presence of objective realities, not be merely phantasmagoria produced by the unconscious activity of the Ego, or otherwise conjured up before his mental eye? May they not be due to the direct operation of the Divine Being? Might not God excite within the individual all the sensations which he experiences, even though material objects were not? Can purely mental phenomena -phenomena which might take place though there were no such thing as matter-warrant the conclusion that matter exists? It may perhaps be urged that our observer is irresistibly impelled to believe that he is perceiving external objects; but what of that? The felt necessity of affirming the non-ego, is a circumstance both intelligible and important, as we shall presently see, on the doctrine of those who hold that the non-ego is immediately cognized; but the Cosmothetic idealist can make no use of it to serve his purpose. For what impels him to believe in outward objects? His very nature. After all, then, the much-vaunted necessity of believing in material realities, indicates nothing except the manner in which we are constituted, and in which we feel ourselves obliged to think. From considerations such as these, Sir W. Hamilton, in common with the most distinguished and consistent idealists themselves, maintains that if an immediate knowledge of the non-ego be denied, scepticism as to its existence becomes logically unavoidable. No better exemplification could be afforded of the difficulty of saving an external world on idealistic principles, than is furnished by Dr. Thomas Brown. whom Sir William not only criticizes mercilessly for his opinions on sensitive perception, but whom, we may add, he wonderfully delights to kick on all occasions, and who certainly is exposed, on many inviting points, to the toe of an opponent. Dr. Brown expressly avows that the irresistible belief to which we have referred, is the only thing which stands betwixt himself and Pyrrhonism. Assuming on the one hand that matter is not immediately known, he grants on the other that its existence cannot be legitimately inferred from aught that we do immediately know, but that "the sceptical argument, as a mere play of reasoning, admits of no reply." Yet forsooth, we are irresistibly compelled to believe in matter ! We are irresistibly compelled to believe what we have no knowledge of, either mediate or immediate! A miserable thing would Philosophy be, were this truly the issue of her speculations. Alas ! if, after she has inscribed on the portals of her temple the great idea, that only what is known is to be believed, she is found to utter as her very first oracle in the ears of her votaries, that an external world is not known, yet must

be believed, to exist! Admit that a blind faith, a faith without knowledge, is either satisfactory, or all that we can attain to, and Philosophy may break her staff. There is no longer any work for her to do.

If Sir W. Hamilton's views be adopted, scepticism in regard to an external world ceases, as a matter of course. The non-ego, according to him, is immediately known to exist. No proof of the fact is given; none is needed; we are conscious of it; and our consciousness involves its absolute certainty. Consider in what circumstances alone doubt can, by any possibility, be legitimate. Should an object not revealed in consciousness be affirmed to exist, there may be good ground for calling its existence in question; some defect may be capable of being pointed out in the evidence through which a knowledge of it is supposed to be attained; and in such a case, scepticism is not only warantable, but imperative. In regard, however, to the existence of an object revealed in consciousness, scepticism is utterly inadmissible. The data of consciousness-those primary beliefs which do not depend upon reasoning, but are the starting points from which reasoning sets out-cannot be assailed. Not only when considered simply in themselves, as apprehended facts, but also when considered as testimonies to the truth of facts, beyond their own phenomenal reality,\* " they must," Sir W. Hamilton writes, "by us be accepted as true. To suppose their falsehood, is to suppose that we are created capable of intelligence, in order to be made the victims of delusion; that GOD is a deceiver, and the root of our nature a lie." Now, in Sir William Hamilton's opinion, the existence of the non ego is one of the primary data of consciousness, and therefore beyond cavil-" a chield that winna ding, and downa be disputed."-Scepticism might be possible, on the principles of Mallebranche, who seeks to prove by Scripture that a material world exists; or on those of Des Cartes, who reaches the same result through a consideration of the veracity of the Divine Being. A sceptic is at liberty, in either case, to bring to trial the demonstration offered, and to withhold his assent from the conclusion till he has satisfied himself that the proof is good. But on the principles of Sir William Hamilton, the door is shut against scepticism, for he affirms the existence of the nonego on an authority above argument. And, though our consciousness of the non-ego does not, according to him, extend to distant objects, but is confined to the bodily organism, and to extra-organic

<sup>\*</sup>The Hamiltonian doctrine of consciousness, here presented, seems liable to grave objections. For a review of it, by the writer of the present article, see Canadian Journal, N. S., vol. 1., page 379.

objects in proximate relation to the organism-though the observer, for instance, whom we supposed to be sailing among the Thousand Tsles, is not held to be immediately cognizant of the islands by which he is surrounded, but only to know them through inference, mediately-there is nothing at all dangerous to our faith in a material world, in this limitation of the range of consciousness. For why do the various idealistic systems inevitably lead to scepticism ? Because they furnish no basis whatever for our belief in the non-ego. Assuming that we immediately know only what is in the mind, they weary themselves in vain to infer from this the existence of anything without the mind. But Hamilton in affirming that we are conscious of material objects (though not of those which are distant.) destroys scepticism : for however narrow the sphere within which we communicate with an external world, the external world is, on his doctrine positively known to exist; and what we do immediately know of it. forms a foundation on which conclusions can safely be erected, regarding the existence of objective realities out of the reach of our immediate apprehension. "The doctrine of Natural Realism," Sir William writes, "requires no such untenable assumption for its basis," [as that distant realities are immediately perceived]. "It is sufficient to establish the simple fact, that we are competent, as consciousness assures us, immediately to apprehend, through sense the non-ego in certain limited relations; and it is of no consequence whatever either to our certainty of the reality of a material world, or to our ultimate knowledge of its properties, whether by this primary apprehension we lay hold, in the first instance, on a larger or a lesser portion of its contents."

But should it be denied that the existence of the non-ego is revealed in consciousness, what then ? In fact, the whole body of Idealists maintain that consciousness gives no such testimony as Hamilton ascribes to it. How shall we decide this question ? Philosophers, since the time of Kant, have commonly consented to regard universality and necessity as the sure criteria of first truths; and applying these, among other kindred tests, Sir William contends that mankind are universally and necessarily determined to believe that they immediately apprehend the non-ego. No man living—not even a philosopher—can help being fully persuaded, when he perceives, that he is apprehending immediately something finite and extended which is not self, but exists without self. Either, therefore, universality and necessity must be rejected from being criteria of first truths, or the existence of the non-ego must be allowed to be a datum of consciousness. Observe the difference between this use of the criterion of necessity, and the reference which writers like Brown make to the irresistible belief that all men have of an external world. What Brown speaks of is a persuasion of the existence of an object which is not known, and possibly may be non-existent. On the other hand, the necessity which those who hold the non-ego to be revealed in consciousness, allege in support of their views, is just consciousness irresistibly asserting itself. Should it be said that, on this view, the application of the criterion of necessity to settle the question in dispute, involves a petitio principii-inasmuch as the conclusion sought to be established is proved by an appeal to a test, the affirmation of which is not substantially different from the affirmation of the conclusion ; we answer that this objection would undoubtedly be valid, were the immediacy of our apprehension of an external world supposed to be proved (in the proper sense of the term) by the criterion mentioned. But this is not meant. All that is meant is, that the consciousness of an external world irresistibly asserts itself. A datum of consciousness cannot (strictly speaking) be proved by argument to be so; it must be immediately known as such; and if any one deny that a truth, which really forms one of the data of consciousness, is entitled to be regarded in that light, we must content ourselves with requesting him to purge his reflective eye with "euphrasy and rue," and to think again. If he do so, well. He will then recognise, without argument, what even now amidst his hallucination, he is knowing, and irresistibly feeling that he knows.-If not, his scepticism cannot be helped ; reasoning will never drive it out of him; he must be permitted to enjoy it.

Neither Cosmothetic Idealists, nor those who, like Sir W. Hamilton, plead for an immediate apprehension of the external world, suppose that we know matter as absolutely existing; both parties agree that only its properties are known. From the earliest time, a two-fold distinction among the properties of matter had been recognized, corresponding more or less nearly (as stated by different writers) with Locke's distribution of the qualities of bodies into primary and secondary. Sir W. Hamilton adopts a new division; making three distinct classes of qualities, the primary, the secondary, and the secundo-primary; the last being so called, because they possess a double phasis, partaking in one aspect of the nature of the primaries, and in another of that of the secondaries. The grounds on which Sir William proceeds in this entirely original arrangement may be in a measure anticipated from what has been said; and a brief notice of his classification, will virtually involve a summary

VOL. II.--U

a.

# 298 REVIEWS-DOCTRINE OF SENSITIVE PERCEPTION.

of the leading points in his system, and must bring our exposition to a close.

It will be remembered that sensitive perception (taking the expression in its widest sense) apprehends three things-first, (in sensation) the affections of our animated organism-secondly, (in the perception of our organism as material) the relations of mutual outness which these bear to one another-and thirdly, (in the perception of extra-organic objects, not revealed to consciousness as material) resistance offered to the movement of our organism in space. We have here the basis of Sir W. Hamilton's division of the qualities of bodies. Sensation reveals to us the secondaries. The perception of the organism as material, discovers to us the primaries. And the perception of extraorganic resistance makes us acquainted with the secundo-primaries. To begin with the primaries. In being conscious of the relations of our organism to itself in space, we apprehend it as an object not indivisible and unextended like the ego, but such that affections exist in it, mutually external to one another: an object which is also finite, and which may hence be defined as "occupying space and contained in space." This is the definition of matter or body; and whatever properties can be evolved out of this definition, are primary qualities of matter. Thus, figure is a primary quality, because whatever occupies space and is contained in space, must possess figure. It is apparent that the primaries are only in an improper sense termed qualities (or suchnesses); for a body is not, by possessing them, constituted such a body. They do not discriminate one body from another, but belong to all bodies alike. Turn next to the secondaries. In being conscious of organic affections, we apprehend them as differing in kind or quality strictly so called. For example, one affection of the animated organism, apprehended by consciousness, gives the sensation of redness; another, the sensation of acidity -two sensations of a different kind or quality altogether. Now organic affections may be stimulated by causes either within or without the organism. To causes of the former description our attention is seldom powerfully called; but it is necessary on many accounts that the latter sort should be discriminated among themselves, and should receive distinctive names. Accordingly, when we have been led by experience to attribute a particular affection to the stimulating influence of some external body, we ascribe to that body a quality commonly denoted by the same name with the sensation produced in us. Such qualities, collected into a class, form the secondary quali-

ties of bodies. Thus we say that vinegar possesses the secondary quality of acidity, and a rose that of redness, because we suppose that the stimuli which originated the organic affections, in apprehending which we felt the sensations of acidity and of redness, proceeded from the vinegar and the rose respectively. We are entirely ignorant what the secondary qualities in bodies are; we only know the affections of which they are deemed to be the stimulating causes .--As the secondaries are revealed through sensation, and the primaries through the perception of our material organism, so the secundoprimaries are discovered (we said) by the resistance offered to the movement of our organism in space. We are not conscious of this resistance as proceeding from bodies; but after we have been led by induction to believe that it is exerted by bodies, we then reckon resistance to be a quality of bedies. But is it a primary or a secondary quality? It partakes in some sort of the nature of both. As a mode of resistance felt in us, it is allied to the secondaries. As a degree of resistance opposing our locomotive energy, it resembles the primaries. being like them objectively apprehended. It cannot therefore be placed under either of the two previous divisions; but must be constituted into a class by itself, viz : the class of secundo-primaries. Every particular species of resistance or pressure which a body is capable of exerting, against the movement of our organism, or against any other body, is a secundo-primary quality of the body in question.

# GEOLOGY AND MINERALOGY.

# EARTHQUAKES IN CALIFORNIA.

In a paper by Dr. Trask, of San Francisco, published in the May number of Silliman's Journal, it is stated that the number of earthquakes experienced in California in 1856, amounted to sixteen. The shocks, with one exception, appear to have been comparatively slight; and Dr. Trask (writing from San Francisco) observes moreover, that along the coast of Mexico and Central America, to the south of California, there seems to have been a much greater exemption from these phenomena than has been usual in former years. This appears to have been the fact also, throughout the Pacific, Oceanic, and most of the continental islands along the coast of China; while, on the contrary, to the north and northwest, beyond the fifty-fifth parallel, both volcanic and earthquake phenomena appear to have been of more than average intensity. Dr. Trask cites more especially, the neighbour, hood of the Aleutian Archipelago, the north-east coast of Japan, the British and Russian possessions of North America on the Pacific, and the islands of the Sea

#### GEOLOGY AND MINERALOGY.

of Ochotsk. A submarine eruption in the Straits of Ourinack (lat.  $54 \circ 36'$  N., longitude 135' W.) is reported by Captain Newell, of the "Alice Frazer." A column of water was projected upwards to a height of several hundred feet, and immediately following this, immense masses of lava were thrown into the air whilst the sea for miles around, and for many days after, was covered with floating fragments of pumice. The principal earthquake experienced in San Francisco itself, during the year 1856, occurred on the 15th February, at about half-past five in the morning. Several buildings were injured; and the shock appears to have extended over an area of about one hundred and forty-three miles in length, by sixty-six in breadth.

#### ROCK METAMORPHISM.

Professor T. Sterry Hunt, of the Geological Survey of Canada, has lately made known a very interesting illustration of metamorphic phenomena arising from the action of alkaline silicates on carbonate of magnesia or of iron, or earthy carbonates generally. His experiments show that when a mixture of silica and carbonate of magnesia is boiled with carbonate of soda, the silicate of soda, at first formed, is decomposed by the magnesian carbonate; and secondly, that the regenerated carbonate of soda is enabled to take up a new portion of silica: the result being a continued silification of the magnesia through the agency of the alkaline carbonate. Mr. Hunt finds that, if pulverized quartz be boiled for several hours with corbonate of soda and carbonate of magnesia, a large amount of magnesian silicate is formed; and that, if we suppose a solution of alkaline silicate (which will never be wanting among sediments in which feldspar exists) to be diffused through a mixture of siliceous matter and earthy carbonate, we shall have, with a temperature of 112° Faht. or perhaps with less, all the conditions necessary for the conversion of the sedimentary mass into pyroxenite, diallage, serpentine, talc, rhodonite, &c., all of which constitute beds in our metamorphic strata. If, also, aluminous matter be added to the above, the elements of chlorite, garnet and epidote will be present.

#### WATERS OF THE ST. LAWRENCE AND OTTAWA.

Professor Hunt has also communicated to the Philosophical Magazine for April, 1857, analyses of the waters of the St. Lawrence and Ottawa rivers, accompanied by some interesting observations, the concluding portion of which we give below. The subject will be found more fully discussed in the Report of the Geological Survey for 1854, now on the eve of publication.

#### 1. Water of the River St. Lawrence (10,000 parts.)

"The comparison of the two river-waters whose analysis we have just given. shews the following differences :- The water of the Ottawa, containing little more than one-third as much solid matter as the St. Lawrence, is impregnated with a much larger proportion of organic matter derived from vegetable decomposition. and a larger amount of alkalies uncombined with chlorine or sulphuric acid. Of the alkalies in the state of chlorides, the potassium salt in the Ottawa constitutes 32 per cent., and in the St. Lawrence only 15 per cent.; while in the former the silica equals 34, and in the latter 23 per cent. of the ignited residue. The Ottawa drains a region of crystaline rocks, and the alkalies liberated by the decomposition of the feldspar of these rocks give their character to its waters; the extensive vegetable decomposition evidenced by the organic matters in solution. must also contribute a portion of potash; while the basins of the great lakes through which the St. Lawrence flows are excavated in palæozoic strata which abound in limestone, rich in salt and gypsum, and have given to the water of this river that predominance of soda, sulphuric acid and chlorine, which distinguishes it from the Ottawa. The presence of large amounts of silica in river-waters is a fact but recently established. Until the analysis by Deville of the rivers of France (1848), the silica in water had generally been wholly or in great part overlooked ; and, as he suggests, had, from the mode of analysis been confounded with gypsum. The importance in an agricultural point of view of this large amount of dissolved silica, where river-waters are employed for the irrigation of land, is very great; and geologically, the fact is not less significant, as it marks a decomposition of the siliceous rocks by the action of waters holding in solution carbonic acid, and the organic acids arising from the decay of vegetable matter, which, dissolving the lime, alkalies, and magnesia, from the native silicates, liberate the silicic acid in a soluble form.\* Silica is never wanting in natural waters, whether neutral or alkaline, although proportionably less abundant in neutral waters which contain large amounts of earthy ingredients. The alumina, whose presence is not less constant, although in much smaller quantity, appears equally to belong to the soluble constituents of the waters. The amount of dissolved silica annually carried to the sea by the rivers must be very great; yet sea-water, according to Forchhammer, does not contain any considerable quantity in solution; it doubtless goes to form the

<sup>\*</sup> Although this may be true enough to a certain extent, yet, undoubtedly, a large portion of the silica present in the waters of rivers, more especially of such as flow through uncleared districts, is derived from the constant decomposition of the wood of fallen trees, of ferns and other vegetable matters. In the ashes of most ferns, the silica is over 70 per cent., and in those of equiseti, over 50; whilst it averages about 10 or 12 per cent. in the ashes of the bark, wood, and leaves (taken together) of our common pines. E.J.C.

#### GEOLOGY AND MINERALOGY.

shields of Infusoria, and may play an important part in the consolidation of the ocean sediments and the silification of organic remains."\*

## AZOIC ROCKS OF CANADA.

Professor Whitney in an article in the May number of Silliman's Journal, takes exception to Sir William Logan's subdivisions of our Azoic rocks. He contends that the so-called Huronian Formation belongs in part to the Polsdam sandstone. and in part to the underlying Laurentian group; and, further, that the latter should simply be called "Azoic," to the exclusion of the term "Laurentian"this term having been already bestowed by Deser on the local, post-tertiary beds of Beauport, and other places, in the valley of the St. Lawrence and elsewhere. Without attempting, in the present place, to discuss the claims of the Huronian rocks to be considered a distinct formation, we may reasonably call in question the justness of that view, which, by collecting all of our unfossiliferous strata into a single group, would represent them as the products of a single epoch or period. Surely, if the Palæozoic age be looked upon as typical of at least four periods in the history of the Earth, a subdivision of some kind may be equally conceded to the formations of the great Azoic age: although from the absence of fossils, the subdivision of these formations may be a work of more difficult attainment. That such will some day be effected however, and to a greater extent than many geologists may at present be willing to allow, we are fully confident. With regard to the term Laurentian as applied to some of these Canadian rocks, we would observe, that, even if the same term were previously applied to the patches of post-tertiary strata alluded to above, its peculiar fitness for the gneissoid rocks of the Laurentian Range and connected country, would fully warrant its retention. On the other hand, we quite agree with Professor Whitney respecting the use of the term "Cambrian." If this term cannot be applied in accordance with the views of Sedgwick to the whole of the lower Silurians (a conclusion becoming more and more apparent every day,) let it be abandoned altogether. Its application to the Huronian formation, or to the Potsdam sandstone as proposed by Sir Charles Lyell, answers no object whatever, and is but little likely, moreover, to be generally adopted.

#### SUPPOSED EMERALDS FROM ALGIERS.

The pale green crystals from the Upper Valley of the Harrach in Algiers, announced as emeralds by M. Ville, have proved to be tourmalines, analogous to the somewhat rare variety met with at St. Gothard, and in Elba. They were first discovered in 1855, in a crystalline limestone associated with gypsum and diorite, about ten miles east of Blidah. (Bulletin de lu Société Géologique de France; tome XIII, page 416.) Most tourmalines when treated with salt-of-phosphorus before the blow-pipe, effervesce and dissolve readily; but this pale green variety, curiously enough, behaves just like the emerald: exhibiting a scarcely perceptible effervescence, and dissolving very slowly.

#### CYSTIDEANS.

Mr. Billings, palæontologist to the Geological Survey of Canada, has discovered in the Chazy limestone near Montreal, a new Cystidean, more or less allied to *Cryptocrinus* by its three basal or pelvic plates, but differing from that genus by

<sup>\*</sup> Some, although probably but a small portion, may be taken up by marine vegetation, as seven percent of silica appears to have been detected in the ashes of *fucus vesiculosus*. The ashes of most sea-weeds, however, contain no more than one or one-and-a-half per cent of silica. E. J. C.

the possession, amongst other peculiarities, of more than two ranges of plates above the pelvic range. Mr. Billings proposes, we believe, for this new genus, the name of *Malocystites*.

The following list of the principal genera of Cystideæ at present known, with their leading characteristics, etc., may not perhaps be unacceptable to some of our readers.

## Cystidece :- principal genera:

1. Echinosphærites, Wallenberg (Spheronites):-Cup of numerous plates with irregularly distributed pores. The principal species comprise: E. Balticus, E. Aurantium, E. Pomum,\* E. Punctatus, and E Granulatus.

2. Caryocystites (Von Buch):-Cup of five ranges or series of plates. Pelvie plates 2 + 2. Included by some palaontologists in Echinospharites.

**3.** Echino-encrinites, Meyer (Sycocystites, V. Buch; Gonocrinites, Eichwald,) eup of 4 ranges of plates. Pelvic range: 3 + 1. Other ranges: 5, 5, 5. Pores bordering rhomboidal areas. Only two openings (?): perhaps one divided to serve both for anal and ovarian orifice.

4. Glyptocystites (Billings:)—Cup of 4 ranges. Pelvie range: 3 + 1. Other ranges: 5, 5. 5. Five (= 4 + 1,) attached arms. Three openings: the ovarian opening without valves (?), and distant from the mouth. Numerous pore-areas, or "pectinated rhombs." We have placed this genus here, because if not identical with *Echino-encrinites*, it is evidently closely allied to it. The numerous poreareas constitute its great distinguishing feature. Where these pore-areas occur in other genera, more than three, or three pairs, are never present.

5. Apiocystites (E. Forbes.) Cup of 4 ranges. Pelvie range of 4 plates. Four attached arms in shallow grooves. One American species (A. elegans): Hall, Pal, New York, vol. II, page 241,) from the Niagara group. Perhaps identical with the A. Pentremiorides of the English survey.

6. Prunocystites (E Forbes.) 7. Pseudocrinites (E. Forbes.)

8. Hemicosmites (Von Buch):—Cup of 4 ranges. Pelvic plates 4. Plates of the other ranges: 6, 9, 8, (at least in the known species.) The three openings in the top range.

9. Pleumocystites (Billings:)—Large plates on only one side of the cup. On the other side a large opening, probably covered by an integument strengthened by numerous small plates. Pelvie range of six plates (= 2 + 2 + 2.) Second half range of three large plates. Third half-range of four plates. Top range (entire) of ten small plates carrying the two arms. Several species from the Trenton limestone of Ottawa.

10. Callocystites (Hall:)—Cup of 4 ranges. Pelvic range of 4 plates ( $\pm 2 + 1 + 1$ .) Second range of 8 plates. Five attached arms. Stem of very thin joints, (at least in the known species :—V. Pal, New York, vol. 2, page 238). One species O. Jewettii, (Hall) from Niagara group.

11. Malocystites :- Mr. Billings' new genus alluded to above.

12. Cryptocrinites, or Cryptocrinus (Von Buch) :- Cup of three ranges. Three

<sup>\*</sup> E. Pomum is viewed by some authors as the type-form of a distinct genus (Sphæronites. an old name revived,) characterised by the presence of two pores, in place of several, on each plate.—E. J. C.

#### CHEMISTRY.

pelvic plates. Five plates in second, and six in top range. C. lævis is the more common species.

13. Calliocrinites (Calliocrinus, d'Orb)? Cup of two ranges. Pelvie range of 5 plates. Apparently a very doubtful genus.

Appendix :-Hemicystites, Hall, (including Agelacrinites: Pal, N. Y., vol. 2, page 245, and also page 355.) Tetragonis, Eichwald (including Ischadites, Murchison; and Receptaculites, Salter. (V. McCoy's Cambridge Museum Fossils, page 62.)

#### CHEMISTRY.

#### NOTE ON THE OXALATE OF MANGANESE,

I have to correct a slight error in my note on the oxalate of mangauese, published in a former number of this journal\*. I have there supposed the formula of Graham's oxalate to be Mn O,  $C^2O^3+5$  aq., whereas, adopting the bibasic character of the acid, it should be  $2 Mn O+C^4O^6+5$  aq.

Souchay and Lenssen have lately (Ann. Ch. u. Ph. April) examined the same salt, and confirm Graham's formula; in the single analysis mentioned in their paper, they found 37,55 p. c. of Mn O, the formula requiring 37,83. According to the formula  $2 \text{ Mn O} + C^4 \text{ O}^6 + 6$  aq, the quantity of Mn O should be 36,09, while my four determinations range from 36,39 to 36,79. The pink hydrate is very prone to lose water in a warm atmosphere, and if not analyzed quickly the amount of Mn O would of course come out too high.

Moreover, the quantity of water lost by the pink salt, at a temperature of 212° was in my experiments 8.75, the formula requiring 9.09, whereas if Graham's formula be adopted the loss should be only 4.78. The extrication of the water takes place easily and rapidly, and cannot therefore be due to a loss of water from the white hydrated salt, which, according to Liebig, loses nothing at 212°, and only after continuous heating, according to Souchay and Lenssen.

I am therefore inclined to retain the formula  $2 \operatorname{Mn} O_+ C^+ O_{+6}^6$  aq.

H. C.

#### BORON.

By the action of aluminum on fused boracic acid, at a high temperature, Wöhler and Deville have obtained boron in the amorphous (already known), the graphitoid, and the crystallized state. The graphitoid boron is obtained by the action of an acid on the boride of aluminum, and appears in the form of spangles, often hexagonal, slightly reddish, and with the form and brilliancy of natural graphite and graphitoid silicon; it is perfectly opaque. The crystallized is obtained in small red or yellow crystals, the form of which cannot be determined, as they seem to be composed of a number of small crystals. These possess a brilliancy and refractive power only comparable to the diamond, and rival it in hardness. When heated it oxidizes only on the surface, not altered by nitre at a red heat, readily acted on by chlorine, and slowly by carbonate of soda at a red heat. It forms alloys with platinum and palladium.

When a filter on which amorphous boron has been dried is inflamed, the boron burns with great ease; the graphitoid variety resists combustion in this way.

<sup>\*</sup> Can. Jour. N. S. vol. ii, pp. 30--32.

#### CHEMISTRY.

#### MANGANESE.

Brunner prepares this metal by the action of sodium on the fluoride. Its specific gravity is 7.138-7.206, unchanged in the air, harder than steel, oxidizes on the surface when heated, like iron, is non-magnetic, dissolves readily in diluted sulphuric acid, and in nitric and hydrochloric acids. From its extreme hardness it may probably find useful applications in the arts.

#### CHROMIUM.

Fremy obtains this metal in crystals of great brilliancy by passing the vapour of sodium over the chloride. The crystals are very hard, and resist the action of the strongest acids.

#### SILVER IN SEA WATER.

It has long been known that sea water contains an appreciable quantity of silver, probably in the form of chloride, dissolved in the chloride of sodium. As such a solution is readily decomposed by metallic copper, Field was induced to examine whether the yellow metal employed in the sheathing of vessels contained more silver after long exposure to sea water than it did when first applied. One specimen from sheathing which had been used for seven years gave as much silver as would amount to upwards of one pound per ton. The original yellow metal could not be obtained for examination, but it undoubtedly could not have contained anything like this quantity. Sheathing, which had been exposed for three years was compared with some of the unused metal; the latter contained about one ounce of silver per ton, the former more than seven ounces.

Various other experiments were made, and in every case a similar difference observed, but in cases where the sheathing had only been exposed a short time, the differences were very slight.

#### MAGNESIUM.

Deville and Caron have prepared this metal in considerable quantities and examined its properties. They find that it resembles zinc in being volatile, and almost at the same temperature. It fuses at about the same temperature as zinc; at a higher point it inflames, and burns like zine, producing a brilliant flame and white flakes. Specific gravity, 1.75.

#### PREPARATION OF METALS.

Deville recommends the use of lime crucibles in the preparation of chromium and manganese, as thereby the presence of silicium is avoided, which is almost always formed when earthen and porcelain crucibles are employed. Charcoal vessels are equally objectionable. Cobalt and Nickel, when prepared in this way, possess very different properties from those usually ascribed to them, cobalt being one of the most ductile and tenacious of metals. Manganese and chromium thus prepared are excessively hard; the latter, when pure, is less fusible than platinum, it dissolves readily in hydrochloric acid, giving a blue solution of Peligot's protochloride.

#### OXIDE OF SILICIUM.

Wöhler found that by heating silicium to a slight red heat in a current of dry hydrochloric acid gas, hydrogen is given off, and a new chloride of silicium formed. It is a very mobile funing liquid, more volatile than the ordinary chloride. Water decomposes it into hydrochloric acid and the new oxide. The latter is white, slightly soluble in water, easily in alkalies, even in ammonia, evolving

#### MISCELLANEOUS.

hydrogen with effervescence, and being converted into silicic acid. When heated in the air it ignites and burns with a very white light.

#### FORMATION OF NITROUS ACID.

Tuttle has found that nitrous acid is formed when copper is oxidized in presence of ammonia; the blue solution obtained by exposing strips of copper and ammonia to the air, contains nitrous acid. None is formed by exposing an ammoniacal solution of black oxide of copper, but a trace is produced by employing the colourless solution of the red oxide.

#### ÆTHYLAMINE.

According to Tuttle this is best prepared by heating a mixture of urea with five parts of sulphovinate of lime and excess of caustic lime. The vapours are passed into muriatic acid, the solution evaporated and treated with a mixture of alcohol and æther, to separate the sal ammoniac. The solution furnishes a deliquescent salt, from which the æthylamine can be obtained by the action of potassa.

ARTIFICIAL FORMATION OF GLYCERINE.

Wurtz has obtained glycerine in the following way: Berthelot's iodized propylene C°H<sup>5</sup>I is treated with excess of bromine, and a tribromide obtained C°H<sup>5</sup>B<sup>3</sup>. This is mixed with acetate of silver, and excess of glacial acet'e acid, and kept for several days at a temperature of  $248^{\circ}-257^{\circ}$  F.; the liquid filtered off, and the bromide of silver washed with æther, the liquid distilled until the temperature rises to  $284^{\circ}$  F., the residue treated with lime and æther. The æthereal solutiou leaves a yellowish oil, which is triacetine, and can be resolved by saponification into acetic acid and glycerine. That the substance was really glycerine was proved by the action of iodide of phosphorus, which gave iodized propylene.

#### LEUCINE AND ALANINE.

Limpricht has found that by distillation leucine is resolved into carbonic acid and amylamine. Alanine yields æthylamine, and glycocine would, in all probability, give methylamine. H. C.

## MISCELLANEOUS.

We are strongly tempted to find a place for the following graceful and humorous metrical tributes paid to one of the most distinguished scientific men of this continent, under our periodical heading of *Ethnology and Archæology*. Ethnological it will be seen the muse has grown, under the inspiration of her theme; and though recognising the event she celebrates as one which looks forward to an antiquity yet to be attained: there is an Archæological treatment of the subject ample enough for all purposes, at least of the comic muse!

On the 28th of May last, the distinguished American savant, Louis Agassiz, attained his fiftieth birth day; and on that pleasant anniversary an assembly of poets, men of science, and loving friends, of Boston and its neighbourhood, met together and celebrated a birth-day dinner, such as those who shared in the enjoyment of it will long keep in fresh remembrance. None who have met with the genial and highly gifted Agassiz, and so learned to appreciate how thoroughly the delightful elements of the companion and friend blend in him, with those of the acute and fearless investigator of science, will fail to appreciate the hearty sincerity and cordial warmth which must have united together the friends gath-

ered round the festive board on the late Anniversary of the Agassiz birth day, "when Hope and Memory kissed," in welcoming him into his fiftieth year. No wonder that the poets found a ready inspiration alike for grave and graceful fancies; and for humorous, yet kindly irony, and playful badinage, such as sports with his favourite ethnic opinions, and humorously hints at the heresice of his scientific views in relation to his Adamic ancestry.

Various impromptu contributions proved the richness of the poetic fancy and humour which the happy occasion excited; while others, from the pens of some of America's most gifted poets, will survive as lasting memorials of the happy festive meeting. The following is the lively contribution of JAMES RUSSELL LOWELL:-

> A health to him who reached to-day Life's height of water shedding, Where Hope and Memory kiss and say Let's keep our golden wedding: To him whose glow the heart could reach Of glaciers that he studied, Who learned whatever fish could teach. Except to be cold-blooded ! To him, who, if our earth were lost, And Nature wanted counsel. Could make it over at less cost From ridge-pole down to groun' sill : Could call the Dodo back to youth, Could call Ornithorynchus, Nay ! were we gone, from just a tooth Could good as new re-think us! To him who every egg has scanned, From roc to flea included. Save those which savants find so grand In nests where mares have brooded! To him, who gives us each full leave (His pedigree amended.) To choose a private Adam and Eve From whom to be descended ! But stay-for chance-come thoughts are best-I meant the health to proffer Of him, our friend there and our guest, And yet not that I offer :--No, rather drink this toast with me. Worth any common dozen : Here's Adam and Eve Agassiz. To whom we owe our cousin!

Such is a good specimen of the gayer fancies which the happy anniversary has called forth. The following piece is graver, more earnest, and as we think, worthy of the occasion, no less than of the pen of America's gifted poet Longfellow:—

It was fifty years ago In the pleasant month of May, In the beautiful Pays de Vaud, A child in its cradle lay.

And Nature, the old nurse took The child upon her knee, Saying: "Here is a story-book Thy Father has written for thee.

#### CANADIAN INSTITUTE.

"Come, wander with me," she said, "Into regions yet untrod; And read what is still unread In the manuscripts of God."

And he wandered away and away, With Nature, the dear old nurse, Who sang to him night and day The rhymes of the universe.

And whenever the way seemed long Or his heart began to fail,

She would sing a more wonderful song, Or tell a more marvellous tale.

So she keeps him still a child, And will not let him go, Though at times his heart beats wild For the beautiful Pays de Vaud :

Though at times he hears in his dreams The Ranz des Vaches of old, And the rush of mountain streams From glaciers clear and cold;

And the mother at home says "Hark! For his voice I listen and yearn; It is growing late and dark, And my boy does not return!"

CANADIAN INSTITUTE.

ELEVENTH ORDINARY MEETING .- 7th March, 1857.

Colonel BARON DE ROTTENBURG, Vice-President, in the Chair.

The following Donations received since last Meeting were announced; and the thanks of the Institute voted to the Donors:

 From B. Gibb, Esq., of Montreal, per A. H. Armour, Esq., : "Two small mummy Crocodiles, from the mummy Pits of Upper Egypt." "Some Egyptian Papyrus from Ancient Thebes."

"A small piece of mummy cloth."

2. From the Regents of New York State Library."

Documents relating to the Colonial History of the State of New York, Holland Documents, 1603, 1656. Vol. I.

4. From Messrs. Gould and Lincoln, per A. H. Armour, Esq., : Annual of Scientific Discovery, 1857. 1 vol.

5. From Hon. J. M. Brodhead, Washington, per A. H. Armour, Esq., : "Official Army Register, United States, for the year 1857." Pamphlet.

"Navy Register of the United States, for the year 1857." Pamphlet.

The following Gentlemen were elected Members :

JOHN MCNAUGHTON, Esq., Lancaster, C. W.

JOHN MORRIS, Esq., Toronto, C. W.

DE. SAMUEL STRATFORD, New Zealand, Corresponding Member.

#### The following papers were then read;

1. By the Rev. Prof. YOUNG, M.A.:

"On Sir David Brewster's supposed law of visible direction in monocular vision, and the corresponding law of visible direction in binocular vision." 2. By Professor WILSON, LL.D:

"Remarks on a specimen of Indian Corn having the male and female flower developed on the same stalk. The specimen was presented to the Institute.

3. By Col. BARON DE ROTTENBURG :

"Report of the Committee appointed to consider a proposition from Lieutenant Ashe, R.N., for the establishment of an Astronomical Observatory at Quebec.

The Report was adopted, and the following draft of a memorial was approved of, and ordered to be transmitted to His Excellency the Governor General, and to the Legislative Council, and the Legislative Assembly, the Council being requested to take the requisite steps for securing the fitting presentation thereof.

The Memorial of the Canadian Institute Incorporated by Royal Charter,-

HUMBLY SHEWETH, — That Your Memorialists have been informed that application has been made to Your Excellency by Lieutenant Ashe, Royal Navy, for an extension of the Astronomical Observatory at Quebec, whereby the same may be rendered more efficient and useful.

Your Memorialists most respectfully beg of Your Excellency to take this application into consideration, and in support of the same they desire humbly to represent to Your Excellency, that Astronomy, while deservedly ranking as the first of sciences, both on account of the certainty of its processes, the brilliancy of its results, and the wide field it offers for investigation, is at the same time that above all others which is most closely connected in its practical bearings with the interests of civilized life and the progress of commercial intercourse; that so fully has this truth been recognized that at the present day there does not exist a kingdom in Europe which has not established one or more National Observatories, while in the United States so strong an interest has been awakened on this point that such institutions are being founded in all parts of the country, of which the recently opened Observatory at Albany is a splendid and notable example.

Your Memorialists believe that even if the practical benefits that would result from the establishment of such an institution were not directly and immediately felt, Canada has now taken such rank among communities that it 'would not consist with her dignity to lag behind in the march of scientific research; but the requirements of her rapidly increasing commerce render this establishment almost a necessity.

Your Memorialists need only refer to the important duties which would devolve on the Observatory in connection with Navigation, such as the determination of true time, the regulation of Chronometers, the correction of Ship-compasses; and here also they might be permitted to recall the great services rendered by a similar institution at Washington, under the conduct of Lieutenant Maury, by his famous Charts and system of Navigation which are producing effects the value of which can hardly be over-rated.

Your Memorialists would also represent that Quebec is peculiarly and fortunately qualified for the site of an Observatory, both from its steady climate, the clearness of its atmosphere and its local advantages of position; and also from its being at once an inland town and a seaport.

#### CANADIAN INSTITUTE.

Your Memorialists would not presume to dictate to Your Excellency the manner in which the object of this petition should be carried out, but they may be permitted to state their opinion that for a sum of Five Thousand Pounds and an annual endowment of One Thousand Two Hundred Pounds, a first-class Observatory could be efficiently and permanently constructed, equipped and maintained.

Your Memorialists, while urging with earnestness on your consideration this prayer, have all confidence in the wisdom and liberality of Your Excellency, and feel assured that should a National Canadian Astronomical Observatory be founded, it will be on a scale commensurate with the importance of the object and the character of the country.

And Your Memorialists as in duty bound will ever pray.

EDWARD J. CHAPMAN, DEROTTENBURG, JOHN LANGTON, 1st Vice-President. 2nd Vice-President. 3rd Vice-President. J. GEORGE HODGINS, Secretary.

TWELFTH ORDINARY MEETING .- 14th March, 1857.

Professor E. J. CHAPMAN, Vice-President, in the Chair.

The following Donation for the Library was presented, and the thanks of the Institute voted to the Donor;

From T. Henning, Esq., :

"Villa and Cottage Architecture," by Calvert Vaux.

The following papers were then read:

 By JAMES H. MORRIS, M.A.,: "Notes of Travel in China."

2. By Col. BARON DE ROTTENBURG:

"Report of the Committee on Prof. Kingston's paper on the use of the Electric Telegraph in giving notice of storms.

. The report of the Committee was adopted, and remitted to the Council to be carried into effect.

3. By Col. BARON DE ROTTENBURG :

"Extract of a letter from Mr. Chalmers of Barrie, F. R. Astronomical Society detailing some observations which he had made on the 26th February, on a supposed volcano in the moon.

THIRTEENTH ORDINARY MEETING .- 21st March, 1857.

Professor E. J. CHAPMAN, Vice-President, in the Chair. The following Gentleman was elected a Junior Member : JAMES BEATTY, Esq.

#### CANADIAN INSTITUTE.

# The following Donations were announced, and the thanks of the Institute voted to the Donors:

1. From the Patent Office, Washington:

"Report of the Commissioners of Patents for 1854: Mechanics. Vol. IL

- 2. From G. W. Allan, Esq.,: "Gould's Trochilidæ."
- 3. From John Gould, Esq.:

" Fifty specimens of Birds."

A letter was read announcing the donation to the Institute by Jesse Ketchum, Esq, of two acres of land on Yonge Street, for the erection of an Astronomical Observatory, on condition that the Institute shall take effectual steps for establishing the same within two years from this date.

The letter was referred to the Committee on the Quebec Observatory.

#### The following papers were then read:

1. By J. H. MORRIS, M.A., :

"Notes of Travel in China." Part II.

"On certain homogeneous characteristics ascribed to the aboriginal tribes of this continent."

3. By JOHN MCNAUGHTON, Esq..:

" Some remarks on the relations of Canada to the adjacent territories."

FOURTEENTH ORDINARY MEETING .- 28th March, 1857.

JOHN LANGTON, M.A.. Vice-President in the Chair.

The following Gentlemen were elected Members:

GEORGE A. PYPER, Esq., Toronto.

WILLIAM MCCABE, Esq, Whitby, C.W.

The following Donation to the Library was announced, and the thanks of the

Institute voted to the Donor:

From the Author:

" Surnames," by B. Homer Dixon, Esq., Boston. Privately printed.

The following papers were then read:

1. By the Rev. A. CONSTABLE GEEKIE:

"On Canadian English."

2. By A. BRUNEL, Esq., C.E.:

"A proposition, in relation to the Desjardin-Bridge Railway accident, to refer the subject of the strength of timber used in railway bridges, to gentlemen connected with the Institute, whose tastes or pursuits are connected with such an inquiry." An interesting discussion arose from this communication, and while it was not deemed expedient to make any special reference of the subject, a wish was expressed that the matter should engage the attention of some members of the Institute, whose practical knowledge qualified them for such an inquiry, and that the results be communicated to the Institute, and published in the Journal.

<sup>2.</sup> By Professor WILSON, LL.D., :

WEAN METBOROLOGICAL RESULTS AT TORONTO FOR THE YEAR 1856. Read before the Canadian Institute 21st February, 1857.

BY PROFESSOR KINGSTON, M. A., DIRECTOR OF THE PROVINCIAL MAGNETIC OBSERVATORY, TORONTO,

The year 1556, was a year of extremes. It was the coldest, the most windy, and the least rainy year of any known in the history of the Observatory, and be omitting two exceptions, one of each kind, it affords instances also of the highest and the least recorded.

Ushered in by a day cold, keen, and of unusual brilliancy, the year commenced with the coldest and nost windy January on record. The mouth was rainless, and showed in creace of the ordinary January thaw. Pebruary and March were more windy respectively, than any previous February and March, the exception of February and March, 1848, and February, 1855, they were colder than the corresponding months of all past years. These two months also, like January, were without and, after an interval, quite unprecedented, of 109 days.

The Spring was backward; the ice did not wholly disappear from the Bay fill the 18th of April, and snow, though in a very slight quantify, fell as late as the 900 for May.

July was the warmest July but one yet known. In Octoher, a fog, remarkable for density, duration and extent, prevailed from the 19th to the 25nd inclusive, and was said to have extended from Chicago as far as Quebee. In November the snow exceeded that of any previous November. December was marked by the snow exceeded that of any previous November. December was marked by December, and by the most temperature that ever occurred in the month of December, and by the most windy day recorded in any mouth whatever, in this or pack pears.

The mean temperature of 1356 was  $42^{\circ}.16$ , which is  $1^{\circ}.90$  below the average of 17 years and the lowest annual mean on record; the nearest approach to it having been  $42^{\circ}.55$  in 3845.

As usual, July was the varmest month in the year; its mean temperature was 69.9. July beside being absolutely, was also relatively the warmest month in the year, estimated, that is, by the excess of its mean temperature be that belonging to the parallel passing through Toronto or to Toronto itself. When considered further, with reference to past years, the mean temperature of July, 1856, was never exceeded by any monthly mean excepting that of July, 1854, which was never exceeded by any monthly mean excepting that of July, 1854, which was never exceeded by any monthly mean excepting that of July, 1854, which was never exceeded by any monthly mean excepting that of July, 1854, which was never exceeded by any monthly mean excepting that of July, 1854, which was never exceeded by any monthly mean excepting that of July,

The coldest month absolutely was February, with a mean temperature of 15.69; the coldest month relatively to the standard of Toronto, was January, with a mean temperature  $7^{\circ}81$  below the arcange. The warmest day was July with a mean temperature 98.77, and the coldest day was Feb. 13 with a mean temperature  $-6^{\circ}88$ .

The maximum temperature of the year, 96°6, occurred on July 17, and, with the exception of that of 24th August, 1854, when it reached 98°1, was higher than any temperature before known at the Observatory. The minimum of the year-la<sup>97</sup>, on Figh 12, was an example of cold never exceeded but in February of the preceding year.

The range of temperature for the year, derived from these two extremes, was 115°3, one never exceeded but by that of 1855, which amounted to 118°2.

The deviations in defeed from the normals and exceeding 20° were nurrarous; but no example countred of a deviation to that extent in zeroes. DALROWFFIRE, The highest reading of the barometer was 30,460 inclus, at

10.30 Å. M. of Dec. 18th, and the lowest 28,459 incluses at 11.40 Å. M. of Dec. 14, thus giving a range (the range also of the whole year) of 2.021 inclose in less than 95 hours. This minimum, 98,459, was identical with that of 1 355, which occurred on the 916 of Dec. and which also was followed by a considerable rise. The mean humidity of the year, 75 of saturation, was rather less than usual.

The mean intuitory of the year, year, year, year stather less than usual, and the distribution of humidity among the different months more than ordinarily equable. Complete saturation occurred only four times—Jan, 9. Oct, and the 11th and 14th of December. The greatest dryness was .30, which occurred at P. M. of Ams. 11th.

occurred at 4 P. M., of Aug. 11th. It will be seen from the table, that the extent of sky clouded was on the average 75 of the whole sky, and rather less than in the two preceding years. Of the different months, November was the most cloudy, and July most free from founds.

The resultant direction of the wind was  $N \ 71^\circ$  W, and the resultant velocity 3.03 miles, or in other words, the actual displacement of air was that which would have been produced by a wind blowing throughout the year from  $N \ 71^\circ$ W, with a constant velocity of 3.03 miles per hour. The mean velocity of the wind, without regard to direction, was 3.31 miles per hour. a velocity exceeding the action velocity of sorts miles per hour.

It as average of nine years by 2.19 miles. The whole dopth of rain that foll during the year, 21.505 inches, was less by upwards fren inches than that of 1855, and more than intentiches below the average of the last 10 years. The depth of ranow was 655 inches, which exceeds the average of the last 10 years. The depth of ranow was 655 inches, but falls short by more than 13 inches of the snow of the preceding year. The rain occupied 3597 hours, and the snow of the svin and the interesting rear.

Prost occurred in every month but in June, July and August. The latest frost in Spring was on Sist May, and the earlist frost in Autumn on Sopt 21. The Bast mow in Spring was on the 90th of May, and the first snow in Autumn on 30th Oct. The Bay of Toronto was frozen over on Dec. 8.

Twenty-five thunder storms only occurred during the year. The most remarkable example was that of the 4th of June, which was accompanied for a short time by a violent fall of hall with stones in many cases more than half an inch in dinately. The storm lasted, with only occasional intermission, from 10 A.M. to 10 P.M., with the wind mostly from the Bast.

Of the 212 nights when the state of the sky was favorable for observing auroras, there were 35 nights only when auroras were seen, and these all belonged to the lowest class, unless that of Oct. 4 be excepted, when the phenomenon was accompanied by considerable manuetic disturbance.

The usual August season for the appearance of falling stars, passed by without any remarkable display, either as regards number or apparent magnitude. In November its sky was not favourable for the exhibition of these meteors.

Raining on 10 days; depth, 1.755 inches; duration of fall, 39.6 hours. 1st-Very stormy day, with occasional Rain and Snow East. cloudy hour observed, 10 p. m.; mean=0.42. 13th-Foggy at 8 a. m. on 14th 6 and 8 a. m. 28th-Thin Ice on the pools at 5.30 a. m. 29th and 30th-Hoar frost at 6 a. m. impossible to see Aurora on 13 nights. 14th-Distant Thunder at 3.50 p.m. South. midnight (perfect) Lowest Barometer . . . **Highest Barometer** North.

last 18 years being 5°7 below the average. It shews also the lowest maximum tem-perature, and with one exception the lowest minimum temperature during the same Temperature-This month was the coldest April that has occurred during the period.

<sup>10.</sup> Rain and Snow-The quantity of rain was small, being 0.783<sup>5</sup>inches below the average; but it was more than compensated by the greated depth of show that fell which was 10.25 inches above the average or about five times the usual depth. The total moisture was thus °246 inches above the mean.

Wind-This was the most windy April on the records of the observatory, the velocity of the wind heing 3.17 miles above the average of ten years. The Resultant Direction and Velocity from 1345 to 1357 inclusive for the month

of April were N. 19º W., 1.93 miles per hour.

# COMPARATIVE TABLE FOR APRIL.

# THE ARIZONA COPPER MINE.

BY JAMES GILBERT.

Read before the Canadian Institute, 13th December, 1856.

Various causes have combined to excite a greatly increasing interest in the mineral wealth of this continent; and while our own valuable, though still unwrought, Canadian copper region naturally forms the pre-eminent object of such interest, as pertaining to ourselves and constituting a source of future enterprise and wealth, it will not probably prove unacceptable to the Members of the Canadian Institute to learn somewhat of the mineral wealth of the south-western regions of this continent of North America, as illustrated by the Arizona mine, one of the richest copper mines hitherto noted in the mineral regions of California. At the same time the history of this mine, while it directs our attention to other depositories of unwrought mineral treasure, abundantly illustrates the obstacles which had to be overcome before such could be turned to profitable account.

The information contained in the following brief notice was acquired during a recent visit to California. The Arizona Copper Mine, is situated in the Gadsden Purchase in latitude 32° north, and longitude 111°45' west; being about 110 miles S. E., from Fort Yuma, and 35 miles from the river Gila.

The Arizona Mining Company was formed with the object of opening certain silver mines, existing in the region of the Arizona moun-

VOL. II.---W

tains, and which according to history had been worked by the Mexicans, at an early period, with extraordinary success. One in particular, known as the Planche de la Plata mine, had a wide reputation, having yielded masses of pure silver, weighing more than twenty arrobas, a Spanish weight of twenty-five pounds. Necessity, however, arising from remoteness of situation, and the war whoop of the savage, had long since occasioned the abandonment of this mine; and it was gradually sinking into oblivion, when attention was directed to it by Count Rousset. This daring Frenchman, having obtained from Santa Anna a grant of the mine in question, made an expedition to Sonora, intending to explore the Arizona mountains in search of silver, and to take possession and work the mine ceded to him.

Great and unforseen difficulties were encountered, and his followers becoming disheartened, after months of toil and privation, he was reluctantly forced to suspend, though not entirely to abandon the enterprise. Meanwhile fresh troubles befel him, which it would be foreign to our present object to enter upon; getting embroiled with the Mexican authorities, his capture, trial and execution were the consequences.

Aware of these circumstances the Arizona Company set out from San Francisco, immediately after its preliminary organization, in the latter part of 1854, with the view of taking possession of the noted silver mine; the Frenchman's right to which, it was assumed, had been confiscated by the manner of his death. Arrived in the Gadsden Purchase, the little band of adventurers, numbering twenty men, well armed, separated into detachments, one of which under Mexican guidance, succeeded in making its way to the location pointed out as the Planche de la Plata mine. There were, however, unmistakable signs of the nearness of hostile Indians, consequently, after spending a little time in examining the plain, which bore evidence of having been superficially dug over, and picking up a lump of virgin silver weighing 21 lbs. they returned to their camp, satisfied that the Planche de la Plata mine was a reality ; but, at the same time, convinced that its appropriation was for the present impracticable, from its remoteness with respect to supplies, and from the hostility of the surrounding Indians. Another portion of the company, arriving at Sonorita, heard of a copper mine forty miles to the north, in a barren and unknown country; proceeding thither, and being struck with indications of the great richness of the mine, they resolved to keep possession; the remainder of the company at length joining them, the further search for silver mines was abandoned. One of the explorers

returned to San Francisco, in February, 1855, with specimens of the ore, and the company was incorporated, under the title of the "Arizona Mining Company;" hence, curiously enough, the endeavours of the association to occupy and open old silver mines, were terminated by the unexpected discovery and possession of a rich copper mine.

In the midst of mountain ridges, principally of porphyry, which rise abruptly from plains dotted here and there with grass, lies the Arizona mine. The green colour of the ore, outcropping on the dark red rock, is perceptible at the distance of a mile; numerous specimens of the cactus-one kind of which, the cereus giganteus, the savarre of the Mexicans, frequently attains the height of forty feet,---together with mezquit and iron wood form the principal vegetable growth. Some of the mountains bear evidence of tremendous igneous action, whilst others are void of all traces of plutonic force. The soil is light and porous, with a superabundance of disintegrated granite. Altogether the scene is lonely and desolate in the extreme; though the perpetual but scanty vegetation prevents it from merit ing the appellation of a desert. Water is obtained from natural reservoirs found in the dark mountain recesses, supplied by the rains, which occur with some regularity during the months of July, August, December, January, and February.

The ores extracted are the gray, black and red oxide, the latter richly impregated with virgin copper. Persons conversant with copper mining admit the ore to be the richest, in the average, of any yet discovered. So far as examined the veins increase in richness and quantity as they remove from the surface. For instance, a vein of red oxide four inches wide at the surface, had, at the depth of fifty feet, reached the thickness of four feet, and became almost exclusively pure copper which lay in a soft rock and was easily worked.

Dr. Webster, a resident of San Francisco, largely interested in the mine, and to whose kind services I am indebted for specimens of the ore, informed me of the existence of a peculiar feature in its vicinity; a high hill known as the iron mountain, but which, more accurate observation and analyzis has since proved to be composed of the black oxide of copper, existing in immense quantities.

The knowledge of the Arizona mine was confined to a few Papago Indians, previous to 1851. In the commencement of that year some Mexicans sent a party of seven labourers to work it; six of whom were surprised and murdered by the Apache Indians. Subsequently several foreigners endeavoured to form companies and settle in its

#### NARCOTIC USAGES AND SUPERSTITIONS

vicinity, but obstacles, incidental to its situation, obliged them to desist. Now, however, that the energetic American has acquired a knowledge of these spots, so great in mineral wealth, and the accents of the English language have been heard in the mountain gorges, and on the plains, amid which such mineral wealth abounds, it seems natural to anticipate that the war whoop of the savage will die away. The Indian will disappear here as elsewhere, after witnessing in vain the advantages of civilization and combined industry, and thus ere long this formidable impediment will cease to baffle the exertions of science and commerce, in turning to account so rich a deposit of mineral wealth.

# NARCOTIC USAGES AND SUPERSTITIONS OF THE OLD AND NEW WORLD.

# BY DANIEL WILSON, LL.D.,

PROFESSOR OF HISTORY AND ENGLISH LITERATURE, UNIVERSITY COLLEGE, TORONTO.

# (Continued from p. 264.)

Amid the endless variety which characterises the form of the ancient Mound Builders' pipes, one general type is traceable through the whole. "They are always carved from a single piece, and consist of a flat curved base, of variable length and width, with the bowl rising from the centre of the convex side, From one of the ends. and communicating with the hollow of the bowl, is drilled a small hole, which answers the purpose of a tube; the corresponding opposite division being left for the manifest purpose of holding the implement to the mouth." The authors of the "Ancient Monuments of the Mississippi Valley," express their conviction, derived from the inspection of hundreds of specimens which have come under their notice, during their explorations of the ancient mounds, that the instrument is complete as found, and was used without any such tube as is almost invariably employed by the modern Indian, and also by the modern perfume-loving oriental when he fills his chibouk with the odorous shiraz or mild latakia. The modern pipe-head of each has a large aperture for the insertion of the tube, whereas in

the ancient examples referred to, the perforation is about one sixth of an inch in diameter, and the mouth-piece flattened, and adapted to the lips, so that we can scarcely doubt the mouth was applied directly to the implement, without the addition of any tube of wood or metal. It is otherwise with examples of pipe-heads carved out the beautiful red pipe stone, the most favourite material for the pipe sculpture of the modern Indian. It would seem, therefore, that the pipe-tube is one of the characteristics of the modern race; if not distinctive of the northern tribes, from the Toltecan and other essentially diverse ancient people of Central and Southern America.

The use of tobacco, from the earliest eras of which we can recover a glimpse, pertained to both; but the pipe-head would appear to be the emblem of the one, while the pipe-stem gives character to the singular rites and superstitions of the other. The incremated pipe-heads of the ancient mound builders illustrate the sacred usages of the one; while the skill with which the Indian medicine-man decorates the stem of his medicine-pipe, and the awe and reverence with which—as will be presently shown,—the whole tribe regard it, abundantly prove the virtues ascribed to that implement of the Indian medicine man's sacred art. May it not be, that in the sacred associations connected with the pipe by the Mound Builders of the Mississippi Valley, we have the indications of contact between the migrating race of Southern and Central America, among whom no superstitious pipe usages are traceable, and the tribes of the north where such superstitions are most intimately interwoven with all their sacred mysteries?

In one, though only in one respect, a singular class of clay pipes, which has come under my notice, agrees with the ancient examples, and would seem thereby still further to narrow the area, or the era of the pipe-stem. During the summer of 1855, I made an excursion in company with the Rev. George Bell, to some parts of County Norfolk, Canada West, within a few miles of Lake Erie, for the purpose of exploring certain traces of the former natives of the locality. We found at various places along the margins of the smaller streams, and on the sloping banks of the creeks, spots where our excavations were rewarded by discovering relics of the rude arts of the Aborigines. These included awls or bodkins, and large needles, made of bone,\*

<sup>\*</sup> Implements of bone, precisely corresponding to some of these, are figured and described by Messrs. Squier and Davis, (page 220,) among the disclosures of the ancient mounds. Such implements, however, have pertained to the rude arts of primitive races in all ages, and where found with other samples of the same pottery in the States, have been supposed to be the implements for working the ornamental patterns on the soft clay.

several stone implements, and a considerable quantity of pottery. The specimens of rude native fictile ware considerably interested me, on account of the close resemblance they frequently bore, not only in material, but in ornamentation, to the ancient pottery of the British barrow.

The potters' art appears to have been practised to a great extent, and with considerable skill, by the ancient races of this continent; nor was it unknown to the Red Indians at the period when their arts and customs were first brought under the notice of Europeans. Adair says of the Choctaws and Natchez, that "they made a prodigious number of vessels of pottery, of such variety of forms as would be tedious to describe, and impossible to name;" and DeSoto describes the fine earthware of the latter tribe, in the seventeenth century, as of considerable variety of composition and much elegance of shape, so as to appear to him little inferior to that of Portugal. The specimens found by me in County Norfolk, and elsewhere in Canada, are heavy and coarse, both in material and workmanship, and neither these nor the objects now to be described, admit of any comparison, in relation to artistic design or workmanship, with those relics of the Mound Builders' arts, or the more recent productions of Indian skill which suggest a resemblance to them.

Accompanying the rude fictile ware, spoken of, were also discovered several pipe-heads, made of burnt clay, and in some examples ornamented, like the pottery, with rude chevron patterns, and lines of dot-work, impressed on the material while soft. But what particularly struck me in these, and also in others of the same type, including several specimens found under the root of a large tree, at the Mohawk reserve on the Grand River, and presented to me by the Indian Chief and Missionary, the late Peter Jones, (Kahkewaquonaby,) was the extreme smallness of the bowls, internally, and the obvious completeness of most of such examples as were perfect, without any separate stem or mouth piece; while if others received any addition, it must have been a small quill, or straw. They at once recalled to my mind the diminutive Scottish "Elfin Pipes," and on comparing them with some of these in my possesion, I find that in the smallest of the Indian pipes the capacity of the bowl is even less than the least of those which, from their miniature proportions have been long popularly assigned to the use of the Scottish Elves. Both the pipes and the accompanying pottery totally differ, as Mr. Kane assures me, from any of the manufactures which have come under his notice among the tribes of the North West, with whom, indeed, the potter's art appears to be wholly unknown.

The pottery thus found along with these diminutive Indian clay pipes, is obviously therefore a relic of former centuries, though exhibiting no such evidence as would necessarily suggest a remote antiquity. Similar examples found to the south of the Great Lakes, are thus described by Mr. Squier, in his Aboriginal Monuments of the State of New York : "Upon the site of every Indian town, as also within all the ancient enclosures, fragments of pottery occur in great abundance. It is rare, however, that any entire vessels are recovered. Those which have been found, are for the most part gourdshaped, with round bottoms, and having little protuberances near the rim, or oftener a deep groove, whereby they could be suspended. A few cases have been known in which this form was modified, and the bottoms made sufficiently flat to sustain the vessel in an upright position. Fragments found in Jefferson County seem to indicate that occasionally the vessels were moulded in forms nearly square, but with rounded angles. The usual size was from one to four quarts ; but some must have contained not less than twelve or fourteen quarts. In general there was no attempt at ornament; but sometimes the exteriors of the pots and vases were elaborately, if not tastefully ornamented with dots and lines, which seem to have been formed in a very rude manner with a pointed stick or sharpened bone. Bones which appear to have been adapted to this purpose are often found. After the commencement of European intercourse, kettles and vessels of iron, copper, brass, and tin, quickly superseded the productions of the primitive potter, whose art at once fell into disuse."\*

In an able summary of the "Archæology of the United States," embodying a resumé of all that has been previously done, Mr. Samuel F. Haven remarks: "In order to estimate correctly the degree of skill in handicrafts possessed by the people who were found in occupation of the soil, we must go back to a time antecedent to the decline in all domestic arts which resulted immediately from intercourse with the whites. So soon as more effective implements, more serviceable and durable utensils, and finer ornaments, could be obtained in exchange for the products of the chase, their own laborious and imperfect manufactures were abandoned."† But just as this reasoning must unquestionably prove in many cases, it fails of application in relation to the absence of the potter's art among the Indians of the North West, for the substitutes found for it are of native manufacture, and present a much greater dissimilarity to the pro-

<sup>\*</sup> Aboriginal Monuments of the State of New York. Page 75.

<sup>+</sup> Smithsonian Contributions. Vol. VIII. Page 155.

ducts of European art. Among the Chinooks, for example, inhabiting the tract of country at the mouth of the Columbia River, the only domestic utensils remarked by Mr. Paul Kane, as creditable to their decorative skill were carved bowls and spoons of horn, and baskets and cooking vessels made of roots and grass, woven so closely as to serve all purposes of a pitcher in holding and carrying water. In these they even boil the salmon which constitute their principal food. This is done by placing the fish in one of the baskets filled with water, into which they throw red hot stones until the fish is cooked. Mr. Kane observes that he has seen fish dressed as expeditiously by this means, as if boiled in the ordinary way in a kettle over a fire.

Keeping in view the evidence thus obtained, it will probably be accepted as a conjecture not without much probability in its favor, that the rude clay pipes referred to, found along with other Canadian relics, and especially with specimens of fictile ware no longer known to the modern Indian, furnish examples of the tobacco pipe in use in the region of the Great Lakes when the northern parts of this continent first became known to Europeans. The application of the old Indian potter's art to the manufacture of tobacco-pipes is a well established fact. Ancient clay pipes of various types and forms have been discovered and described; and in a "Natural History of Tobacco" in the Harleian Miscellany,\* it is stated that: "the Virginians were observed to have pipes of clay before even the English came there; and from those barbarians we Europeans have borrowed our mode and fashion of smoking."

Specimens of another class of clay pipes of a larger size, and with a tube of such length as obviously to be designed for use without the addition of a pipe-stem, have also been repeatedly met with, and several from Canadian localities are in my own possession. In the Edinburgh Philosophical Journal, February, 1848, Dr. E. W. Bawtree describes a series of discoveries of sepulchral remains, accompanied with numerous Indian relics, made in the district to the south of the River Severn, between Lake Simcoe and Georgian Bay. These included specimens of the large *pyrulæ*, or tropical shells of the Florida Gulf, copper kettles, arrow heads, bracelets and other personal ornaments, of copper, beads of shell and red pipe-stone, and also various examples of the larger clay pipes : which no doubt belong to an era subsequent to intercourse with Europeans, as the same discoveries included axe-heads and other relics of iron. Another ex-

<sup>\*</sup> Vel. I. Page 535. Quoted in Notes and Queries, vol. VII. Page 230.
ample of this larger form of clay-pipe figured in Dr. Schoolcraft's "History of the Indian Tribes;"\* was also found within the Canadian frontier, in the peninsula lying between Lakes Huron and Erie. It was discovered in an extensive sepulchral ossuary in the township of Beverly, which contained numerous Indian relics, and among others, specimens both of the pyrula perversa and purula spirata. Mr. Paul Kane possesses another pipe of the same class, trumpet shaped at the bowl, and unusually well baked, which was dug up in the vicinity of the Sault St. Marie, at the entrance to Lake Superior ; so that this class of relics of the nicotian art, appears to be pecularily characteristic of the Canadian frontier. Some, at least, of these Canadian pipes are of no very remote antiquity, but it is curious to note that in form they bear a nearer resemblance than any figured or described among American antiquities, to such as are introduced in ancient Mexican paintings; † nor are examples wanting of a more antique style of art. One specimen figured by Mr. Squier in his "Aboriginal Monuments of the State of New York,"‡ is thus described: "It was found within an enclosure in Jefferson County. It is of fine red clay, smoothly moulded, and two serpents rudely imitated, are represented coiling round the bowl. Bushels of fragments of pipes have been found within the same enclosure. Some appear to have been worked in the form of the human head, others in representations of animals, and others still in a variety of Some pipes of precisely the same regular forms. . material and of identical workmanship with those found in the ancient enclosures, have been discovered in modern Indian graves in Cayuga County. One of these in the form of a bird, and having eves made of silver inserted in the head, is now in the possession of the author."

Pipes of baked clay of a character more nearly approximating to the sculpture of the mounds, are figured in Messrs. Squier and Davis's work. In style of art, however, they are greatly inferior. Of two of these (Figs. 76, 77, page 194,) it is remarked: "They were ploughed up in Virginia at a point nearly opposite the mouth of the Hocking river, where there are abundant traces of an ancient people, in the form of mounds, embankments, &c. One represents a human head, with a singular head-dress, closely resembling some of those worn by the idols and sculptures of Mexico. The other represents some animal coiled together, and is executed with a good deal

<sup>\*</sup> Vol. I. Plate VIII. Figs. 5 and 6.

<sup>&</sup>lt;sup>†</sup>Lord Kingsborough's Mexican Antiquities. Vol. IV. Plates 17, 57. <sup>‡</sup>Plate 76, Fig. 9.

of spirit." The latter remark, however, is scarcely borne out by the accompanying illustration, and it seems by no means improbable that these objects furnish specimens of the Indian arts of Virginia in the time of Raleigh. They certainly present no such marked characteristics as to justify their classification with the ingenious sculptures of the Mound Builders. The same remarks apply to examples procured by Schoolcraft, Squier, and other writers; and among such may be included two clay pipes, one of them found in a mound in Florida, and the other in South Carolina, and both described in the "Ancient Monuments of the Mississippi Valley."\* Most of the ancient clay pipes that have been discovered are stated to have the same form; and this, it may be noted, bears so near a resemblance to that of the red clay pipe used in modern Turkey, with the cherry-tree pipe-stem, that it might be supposed to have furnished the model. The bowls of this class of ancient clay pipes are not of the miniature proportions which induce a comparison between those of Canada and the early examples found in Britaia; neither do the stone pipe-heads of the Mound Builders, suggest by the size of the bowl, either the self denying economy of the ancient smoker, or his practise of the modern Indian mode of exhaling the fumes of the tobacco, by which so small a quantity suffices to produce the full narcotic effects of the favorite weed. They would rather seem to confirm the indications derived from other sources, of an essential difference between the ancient smoking usages of Central America and of the Mound-Builders, and those which are still maintained in their primeval integrity among the Indians of the North West.

Great variety of form and material distinguishes the pipes of the modern Indians; arising in part from the local facilities they possess for a suitable material from which to construct them; and in part also from the special style of art and decoration which has become the traditional usage of the tribe. The favourite red pipe-stone of the *Couteau des Prairies*, has been generally sought after, both from its easiness of working and the beauty of its appearance. The region of its celebrated quarries is connected with curious Indian traditions, and the locality appears to have been consecrated for many generations, as a sacred neutral ground whereon parties of rival tribes might freely assemble to supply themselves with the material requisite for their pipe manufacture, as secure from danger as when the peace-pipe has been smoked, and the tomahawk buried by the Chiefs of the Indian nations. A pipe of this favourite and beautiful

<sup>\*</sup> Smitheonian Contributions. Vol. I. Page 194. Fig. 80.

material, found on the shores of Lake Simcoe, and now in my possession, measures five and three quarter inches in length, and nearly four inches in greatest breadth, yet the capacity of the bowl hollowed in it for the reception of tobacco is even less than in the smallest of the "Elfin Pipes." In contrast to this, a modern Winnebago pipe recently acquired by me, made of the same red pipe stone, inlaid with lead and executed with ingenious skill, has a bowl of large dimensions illustrative of Indian smoking usages modified by the influence of the white man.

From the red pipe stone, as well as from limestone and other harder rocks, the Chippeways, the Winnebagos, and the Siouxs, frequently make a peculiar class of pipes, inlaid with lead. Mr. Kane has in his possession an ingeniously carved red stone Sioux pipe, in form of a human figure, lying on the back, with the knees bent up towards the breast, and head thrown forward. The hollowed head forms the bowl of the pipe, while the tube is perforated through the annus; as is the case with another, but much ruder example of pipe sculpture, carved from a light colored sandstone found on the Niami River, Ohio.\*

The Chinook and Puget Sound Indians, who evince little taste in comparison with the tribes surrounding them, in ornamenting their persons or their warlike and domestic implements, commonly use wooden pipes. Sometimes these are elaborately carved, but most frequently they are rudely and hastily made for immediate use; and even among these remote tribes of the flat head Indians, the common clay pipe of the fur trader begins to supersede such native arts.

Among the Assinaboin Indians a material is used in pipe-manufacture altogether peculiar to them. It is a fine marble, much too hard to admit of minute carving, but taking a high polish. This is cut into pipes of graceful form, and made so extremely thin, as to be nearly transparent, so that when lighted the glowing tobacco shines through, and presents a singular appearance when in use at night or in a dark lodge. Another favourite material employed by the Assinaboin Indians is a coarse species of jasper also too hard to admit of elaborate ornamentation. This also is cut into various simple but tasteful designs, executed chiefly by the slow and laborious process of rubbing it down with other stones. The choice of the material for fashioning the favourite pipe, is by no means invariably guided by the facilities which the location of the tribe affords. A suitable stone for such a purpose will be picked up and carried hundreds of miles. Mr.

<sup>\*</sup> Monuments of the Mississippi Valley. Page 247. Fig. 146.

Kane informs me that, in coming down the Athabaska River, when drawing near its source in the Rocky Mountains, he observed his Assinaboin guides select the favourite blueish jasper from among the water worn stones in the bed of the river, to carry home for the purpose of pipe manufacture, although they were then fully five hundred miles from their lodges. Such a traditional adherence to a choice of material peculiar to a remote source, may frequently prove of considerable value as a clue to former migrations of the tribe.

Both the Cree and the Winnebago Indians carve pipes in stone, of a form now more frequently met with in the Indian curiosity stores of Canada and the States than any other specimens of native carving. The tube, cut at a sharp right angle with the cylindrical bowl of the pipe, is ornamented with a thin vandyked ridge, generally perforated with a row of holes, and standing up somewhat like the dorsal fin of a fish. The Winnebagos also manufacture pipes of the same form, but of a smaller size, in lead with considerable skill.

Among the Cree Indians a double pipe is occasionally in use, consisting of a bowl carved out of stone without much attempt at ornament, but with perforations on two sides, so that two smokers can insert their pipe-stems at once, and enjoy the same supply of tobacco It does not appear, however, that any special significance is attached to this singular fancy. The Saultaux Indians, a branch of the great Algonquin nation, also carve their pipes out of a black stone, found in their country, and evince considerable skill in the execution of their elaborate details. In the curious collection of pipes now in the possession of G. W. Allan, Esq., and including those obtained by Mr. Kane among the Indians of the north-west, are two Chippeway pipes carved by the Indians bordering on Lake Superior, out of a dark close-grained stone, easily wrought and admitting of considerable minuteness of detail. One of these, (Plate II. Fig. 2,) measuring six and a half inches long, consists of a quadrangular tube, from which rises the bowl in the shape of a human head, of very sphynx-like aspect; and with white beads inserted for the eyes; behind this an Indian seated on the ground holds his hands to each side of the head, (colossal in proportion to him,) in front is another Indian seated on a chair, and before him stands a third figure neatly carved out of the red pipe stone, while between them is a miniature barrel cut from a white stone found chiefly on St. Joseph's Island. All the figures are well proportioned and carved with considerable minuteness of detail. Some of the details in this example-the chair and the barrel,-are obviously borrowed from European models,

but the general design is purely Indian; the figures are further completed with native head dresses of feathers, and the whole conception and execution well illustrate the usual style of the more elaborate Chippeway pipe sculptures.

One of the most celebrated of these Indian pipe sculptors is Pabahmesad, or the Flier, an old Chippeway still living on the Great Manitouanin Island in Lake Huron; but more generally known as Pwahquneka: the Pipe Maker, literally "he makes pipes." Though brought in contact with the Christian Indians of the Mahnetooahning, or Manitoulin Islands, Dr. O'Meara informs me that he resolutely adheres to the pagan' creed and rites of his fathers, and resists all the encroachments of civilization. His materials are the muhkuhdapwahgunahbeck, or black pipe-stone of Lake Huron, the wahbepwahgunahbeck, or white pipe-stone, procured on St. Joseph's Island, and the miskopwahqunahbeck, or red pipe-stone of the Couteau de Prairies. His saw, with which the stone is first roughly blocked out, is made by himself out of a bit of iron hoop, and his other tools are correspondingly rude; nevertheless the workmanship of Pabahmesad shows him to be a master of his art. One of the specimens of his skill has been deposited by Dr. O'Meara in the museum of Trinity College, Dublin, which, from the description I have received, appears to correspond very closely to the example figured on plate II. Another of the Chippeway black-stone pipes in Mr. Allan's collection is a square tube terminating in a horse's head, turned back, so as to be attached by its nose to the bowl of the pipe, and on the longer side of the tube two figures are seated, one behind the other, on the ground, with their knees bent up, and looking towards the pipe bowl. A different specimen of the Chieppeway pipe, brought from the north-west by Mr. Kane, is made from the root of a red deer's horn, inlaid with lead, as in the red pipe-stone and limestone pipes already referred to as made by the Chippeways, the Winnebagos, and the Siouxs.

But the most remarkable of all the specimens of pipe sculpture executed by the Indians of the north-west, are those carved by the Babeen, or big-lip Indians; so called from the singular deformity they produce by inserting a piece of wood into a slit made in the lower lip. The Babeen Indians are found along the Pacific Coast, about latitude 54° 40', and extend from the borders of the Russian dominions east-ward nearly to Frazer River. Some of the customs of the Babeen Indians are scarcely less singular than that from whence their name is derived; and are deserving of minute comparison with the older practices which pertained to the more civilized regions of the continent. This is especially the case in relation to their rites of sepulture, wherein they make a very marked distinction between the sexes. Their females are wrapped in mats, and placed on an elevated platform, or in a canoe raised on poles, but they invariably burn their male dead.

The pipes of the Babeen, and also of the Clalam Indians occupying the neighbouring Vancouver's Island, are carved with the utmost elaborateness, and in the most singular and grotesque devices, from a soft blue claystone or slate.

Their form is in part determined by the material, which is only procurable in thin slabs; so that the sculptures, wrought on both sides, present a sort of double bas-relief. From this, singular and grotesque groups are carved, without any apparent reference to the final destination of the whole as a pipe. The lower side is generally a straight line, and in the specimens I have examined they measure from two or three, to fifteen inches long; so that in these the pipe-stem is included. A small hollow is carved out of some protruding ornament to serve as the bowl of the pipe, and from the further end a perforation is drilled to connect with this. The only addition made to it when in use is the insertion of a quill or straw as a mouth piece. One of these shewn on Plate II., Fig. I., is from a drawing made by Mr. Kane, during his residence among the Babeen Indians. The original measured seven inches long. Plate III., is copied from one of the largest and most elaborate of the specimens brought back with him; it measures nearly fifteen inches long, and supplies a highly characteristic example of Babeen art.

Messrs. Squier and Davis conclude their remarks on the sculptures of the mounds, by observing: "It is unnecessary to say more than that, as works of art, they are immeasurably beyond anything which the North American Indians are known to produce, even at this day, with all the suggestions of European art, and the advantages afforded by steel instruments. The Chinooks, and the Indians of the north-western coast, carve pipes, platters, and other articles, with much neatness, from slate. We see in their pipes, for instance, a heterogeneous collection of pulleys, cords, barrels, and rude human figures, evidently suggested by the tackling of the ships trading in those seas. . . . . The utmost that can be said of them is, that they are elaborate, unmeaning carvings, displaying some degree of ingenuity. A much higher rank can be claimed for the Moundsculptures; they combine taste in arrangement with skill in workman-

334 -

ship, and are faithful copies, not distorted caricatures, from nature. So far as fidelity is concerned, many of them deserve to rank by the side of the best efforts of the artist-naturalists of our own day."\*

This descriptive comparison with the arts of the Indians of the north-west coast is based, as the illustrations given here (Plates II. and III.) suffice to show, on deductions drawn from the examination of specimens very different from those which have been brought from the same localities, or investigated in the hands of the native sculptors, and obviously constitute the true illustrations of Indian skill and artistic design. In addition to these, however, among the varied collection of Indian relics brought by Mr. Kane from the north-west coast, there is one of the ingenious examples of imitative skill referred to by Mr. Squier, which was procured on Vancouver's Island. But while this exhibits evidence of the same skillful dexterity as the other carvings in the blue pipe-slate of the Clalam and Babeen Indians, it presents the most striking contrast to them. alike in design and style of art. It has a regular bowl, imitated from that of a common clay pipe, and is decorated with twisted ropes. part of a ship's bulkhead, and other objects-including even the head of a screw-nail,-all equally familiar to us, but which no doubt attracted the eye of the native artist from their novelty. Very different from this are the genuine native pipes. They are composed of varied and elaborate devices, including human figures, some of them with birds' and beasts' heads, and frequently presenting considerable accuracy of imitative skill. The frog is a favourite subject. represented generally of the same size as the accompanying human figures, but with a very spirited and life-like verisimilitude. In some of the larger pipes, the entire group presents much of the grotesque exuberance of fancy, mingled with imitations borrowed direct from nature, which constitute the charm of the Gothic ecclesiastical sculptures of the thirteenth century. The figures are grouped together in the oddest varieties of posture, and ingeniously interlaced, and connected by elaborate ornaments; the intermediate spaces being perforated, so as to give great lightness of appearance to the whole. But though well calculated to recall the quaint products of the medieval sculptor's chisel, so far are these Babeen carvings from suggesting the slightest resemblance to European models, that when first examining them, as well as specimens in bone and ivory from the same locality,-and still more so, some ivory carvings executed by the Tawatin Indians on Frazer River.-I was struck with certain

<sup>\*</sup> Monuments of the Mississippi Valley, p. 272.

resemblances to the peculiar style of ancient Mexican Art. Such resemblances may be fanciful or accidental. To me at least they were suggested by no preconceived theory of Mexican migration, as investigations in another direction have inclined me to adopt ideas even less suggestive of such than those generally set forth by American ethnologists. But while the sculptured Babeen and Clalam pipes cannot be compared to some of the more faithful imitations of objects of nature from the mounds, they furnish very noticeable proofs of imitative skill, and are well worthy of consideration as specimens of modern native art, which, if found in the ancient mounds, would have excited no less wonder and admiration than many of the relics figured from among their disclosures.

But there is another conclusion, of more general application, suggested to me by these Babeen sculptures. They are deserving of special consideration, from illustrating, in some respects, the just method of inductive history, as derived from ancient relics. Struck with the discrepancy which every careful investigator of the subject must notice between the elaborate art of the finer sculptures, and especially the pipe-heads of the mounds, and any other traces of the skill and civilization of their builders, Mr. Haven assumes a foreign origin for all such sculptures, while others have inferred from them a native civilization in the Mississippi and Ohio Valleys, corresponding in all respects to these isolated examples of art; just as, from a rude but graceful Greek vase, we can infer the taste of a Callicrates or a Phidias. But it is important to note, that while the Babeen sculptor executes a piece of pipe-carving so elaborate and ingenious as justly to excite our wonder and admiration, it furnishes no test of his general progress in arts or civilization, for, on the contrary, he is ruder and more indifferent to the refinements of dress and decoration than many Indian tribes who produce no such special examples of ingenious skill. Some of the conclusions which such facts suggest will, I suspect, be found applicable to not a few of the deductions derived by European archeologists from isolated examples of primitive art.

The pipe, however, which presents so many and characteristic forms, among the Indian tribes of the far west, whatever may have been its importance in ancient times, is no longer the special object of sacred associations. It is to the pipe-stem that the modern Indian attaches that superstitious veneration which among the Mound Builders would appear to have pertained to the pipe itself. The medicine pipe-stem is the palladium of the tribe, on which depends its safety in peace and its success in war, and it is accordingly guarded with all the veneration, and surrounded with the dignity, befitting so sacred an institution; while, in its use in the war-council, or in the medicine dance, so long as the proper and consecrated pipe-stem is employed, it matters not whether the pipe itself be of the richest carving of which the red stone of the *couteau des prairies* is susceptible, or be the begrimed stump of a trader's English "clay."

The medicine pipe-stem carrier is accordingly an office of great dignity in the tribe, and its holder is endowed with special, though somewhat burdensome, honors and privileges. A highly ornamental tent is provided for his use, and frequently he is required to have so many horses as renders the office even more onerous than honourable. A bear-skin robe is set apart for wrapping up the medicine pipe-stem, when carried, and for laying it on while exposed to view. When wrapped up in its covering, the pipe-stem is usually carried by the favourite wife of the dignitary, while he himself bears in his hands-and not unfrequently on his head - the medicine bowl, out of which he takes his food. But though the sacred pipe-stem is almost invariably borne by the wife of the Indian dignitary, it is never allowed to be uncovered in the presence of a woman, and should one even by chance cast her eyes on it when thus exposed, its virtues can only be restored by a tedious ceremony, designed to counteract the evil effects and to propitiate the insulted spirit. If the stem is allowed to fall to the ground, whether designedly or from accident, it is in like manner regarded as an omen of evil, and many elaborate ceremonies have to be gone through before it is reinstated in its former favor and beneficent influence. Mr. Kane met with a young Cree half-breed who confessed to him that, in a spirit of daring scepticism, he had once secretly thrown down the medicine pipe-stem and kicked it about; but soon after its official carrier was slain, and such misfortunes followed as left no doubt on his mind of the awful sacredness pertaining to this guardian and avenger of the honor of the tribe. The sacredness which attaches to the medicine pipe-stem pertains in part also to its bearer. Many special honors are due to him, and it is even a mark of disrespect, and unlucky, to pass between him and the fire.

At Fort Pitt, on the Sascatchewan River, Mr. Kane informs me that he met with Kea-keke-sacowaw, the head chief of the Cree nation, then engaged in raising a war party to make war on the Blackfeet. He had accordingly eleven medicine pipe-stems with

VOL. II.-X

him, gathered from the different bands of the tribe who had already enlisted in the cause, and each committed to him by the medicineman of the band. Armed with these sacred credentials, he proceeds through the encampments of his nation, attended by a few of his own immediate followers, but without the pipe-stem bearers, whose rights and privileges pass for the time being to the chief. Whenever he comes to an encampment he calls on the braves to assemble. tells them he is getting up a war party, recounts to them the unavenged wrongs of the tribe, recalls the names of those slain in former feuds with the Blackfeet, and appeals to them to join him in revenging their death. Throughout such an oration the tears stream down the cheeks of the excited orator, and this is styled "crying for war." On such occasions the medicine pipe-stems are not uncovered, but Mr. Kane having persuaded the Cree Chief to sit for his portrait, he witnessed the ceremony of "opening the medicine pipestem." as it is called, and during its progress had to smoke each of the eleven pipes before he could be allowed to commence his work. His spirited portrait represents the grim old chief, decorated with his war-paint, and holding in his hand the medicine pipe-stem, elaborately adorned with the head and plumes of an eagle.

In the grave ceremony of opening the medicine pipe-stem, the Crees make use of a novel addition to the tobacco. It is procured from the leaves or fibres of a species of cedar or spruce, which, when dried and burnt, yields a very pleasing fragrance. A handful of this was thrown on the fire in the middle of the room, and filled it with the fragrant smoke, and some of the same was sprinkled on the top of the tobacco each time one of the medicine pipe-stems was used.

All this ceremonial, and the peculiar sanctily attached to the pipestem, apart from the pipe, are special characteristics of the Red Indian of the North West, of which no trace is apparent in the singular memorials of the ancient Mound Builders, or in the sculptures and paintings of Mexico. Throughout the whole elaborate illustrations of Lord Kingsborough's great work it is difficult to discover a trace of Mexican usages connected with the tobacco-pipe, and in no one can I discern anything which appears to represent a pipe-stem. In volume IV, plate 17, of a series copied from a Mexican painting preserved at Pass, in Hungary, a figure coloured as a black carries in his hand a plain white pipe, already referred to as somewhat of the form of the larger clay pipes found in Canada and in the State of New York, and from the bowl rises yellow flames. On plate 57 of the same volume, copied from a Mexican painting in the Borgian Museum, in the College of the Propaganda at Rome, may be seen another figure, holding what seems a small clay tobacco pipe, from whence smoke proceeds. One or two other pictures appear to represent figures putting the green tobacco leaf, or some other leaf, into the pipe, if indeed the instrument held in the hand be not rather a ladle or patera. But any such illustrations are rare, and somewhat uncertain; and it appears to be undoubted that the tobacco pipe was not invested in Central America with any of those singular and sacred attributes which we must believe to have attached to it among the ancient Mound Builders of the Mississippi Valley; and which under other, and no less peculiar forms, are reverently maintained among the native tribes of the North-West, constituting one of the most characteristic peculiarities of the American aborigines, and one well deserving of the careful study of the Ethnologist.

Assuming it as a fact, demonstrated by a variety of independent evidence, that the singular practice of smoking narcotics originated among the native tribes of America. and was communicated for the first time to the Old World, after its discovery by Columbus, it becomes a subject well worthy of consideration how rapid and universal was the diffusion of this custom throughout the world. Not only have Europe and Asia, in later times, disputed with America the origin of this luxurious narcotic art; but travellers who return from the mysterious tropical centre of old Africa find there, in like manner, the use of the tobacco pipe, among tribes to whom the sight of the first white man is strange and repulsive. Such facts are worthy of very careful consideration by the Ethnologist. They prove how fallacious is that mode of reasoning, which, in treating of the natural history of man, takes no account of the predominating influences of reason, intellect, and experience, as manifested even among the rudest savages ; and seeks to apply the same law to man as the lower animals. They serve also to illustrate the indirect means by which the influences of a remote civilization may be extended, and thereby to explain some of the singular coincidences with which the Archæologist is familiar, in the traces of widely diffused primitive arts.

The daring traveller Charles John Andersson, the first explorer of the country of the Damaras, in his "Lake Ngami," furnishes the following interesting account of the African use of the weed :

"The Hill-Damaras subsist chiefly upon the few wild roots which their sterile

neighbourhood produces. Most of them, however, manage to raise a little tobacco, for which they have a perfect mania, and which they value nearly as much as the necessaries of life.

"They also cultivate 'dacka,' or hemp, not as with us, for its fibre, but for the sake of the young leaves and seeds, which they use as a substitute for tobacco, and which is of the most intoxicating and injurious character. It not unfrequently happens, indeed, that those who indulge too freely in the use of this plant are affected by disease of the brain.

"The manner in which the Hill-Damaras smoke is widely different from Hindu, Mussulman, or Christian. Instead of simply inhaling the smoke, and then immediately letting it escape, either by the mouth or nostril, they swallow it deliberately. The process is too singular to be passed over without notice. A small quantity of water is put into a large horn,-usually of a Koodoo,-three or four feet long. A short clay pipe, filled either with tobacco or dacka, is then introduced, and fixed vertically into the side, near the extremity of the narrow end, communicating with the interior by means of a small aperture. This being done, the party present place themselves in a circle, observing deep silence; and with open mouths, and eyes glistening with delight, they anxiously abide their turn. The chief man usually has the honor of enjoying the first pull at the pipe. From the moment that the orifice of the horn is applied to his lips he seems to lose all consciousness of everything around him, and becomes entirely absorbed in the enjoyment. As little or no smoke escapes from his mouth, the effect is soon sufficiently apparent. His features become contorted, his eye glassy and vacant, his mouth covered with froth, his whole body convulsed, and in a few seconds he is prostrate on the ground. A little water is then thrown over his body, proceeding not unfrequently from the mouth of a friend; his hair is violently pulled, or his head unceremoniously thumped with the hand. These somewhat disagreeable applications usually have the effect of restoring him to himself in a few minutes. Cases, however, have been known where the people have died on the spot, from overcharging their stomachs with the poisonous fumes. The Ovaoherero use tobacco in a similar manner, with this difference only, that they inhale the smoke simply through short clay pipes, without using water to cool it, which of course makes it all the more dangerous."

It would seem, alike from the American and the African modes of using the tobacco or other narcotics in smoking, and no less so from the Chinese and Malay employment of opium in a similar manner, that the primitive use of such among all races has been attended with gross intemperance. The inference, therefore, is probably not an illegitimate one, which ascribes the small size of the oldest British tobacco pipes, not to the economy or moderation of Elizabethan and Jacobite smokers, but rather to their practising the nicotian art in close imitation of its wild forest originators. This is nowhere more curiously and discriminatingly indicated than in its prescription for the cure of the mental disorder treated of by the quaint author of "The Anatomy of Melancholy," himself evidently a lover of the weed: "Tobacco, divine, rare, superexcellent tobacco, which goes far beyond all the panaceas, potable gold, and philosopher's stones, a sovereign remedy to all diseases. A good vomit, I confess; a virtuous herb, if it be well qualified, opportunely taken, and medicinally used; but as it is commonly abused by most men, which take it as tinkers do ale, 'tis a plague, a mischief, a violent purger of goods, lands, health; hellish, devilish, and damned tobacco, the ruin and overthrow of body and soul !' Such a description of the extent to which tobacco was "commonly abused," in the early part of the seventeenth century (1621) is only explicable by such modes of partaking of it as still prevail among savage tribes, for scarcely even the grossest excesses of the modern smoker and chewer would admit of such terms of denunciation.

The growing size of the tobacco pipe, as it approaches the era of the Revolution, indicates the introduction of a contemporaneous nicotian revolution also, which adapted the pipe of the Indian medicine-man to the philosophical reveries of an English Newton; and within a century from Zacharie Boyd's association of tobacco with the dissipation of "The wine pint," enabled the devout author of the "Gospel Sonnets," to superadd to these his "Smoking Spiritualized : inserted as a proper subject of meditation to smokers of Tobacco; the first part being an Old Meditation upon smoking Tobacco; and the second a new addition to it, or Improvement of it."\* In his "improvement" of his text the grave divine indulges in nicotian similes, such as, from less reverent hands, would seem profane; comparing the "naughty foreign weed" to "the plant of great renown," to "Jesse's flower" and "Sharon's Rose !" and "The smoke, like burning incense," to devout prayer; closing each stanza with the refrain :

#### "Thus think, and smoke Tobacco."

In this the fanciful moralist "improved" on an old song, which has been traced to the early part of the seventeenth century, and is still preserved on more than one Broadside of dates as early at least as 1670 and 1672. In the former of these it bears the initials "G. W." supposed to be those of George Wither, who is reputed to have found solace in the luxury it celebrates. This unlucky puritan poet, who died in 1667, is said by his unloving biographer. Anthony A'Wood, to have owed his life, on one occasion, to a bon-mot of a

<sup>\* &</sup>quot;Gospel Sonnets, or Spiritual Songs, in six parts, concerning Creation and Redemption, Law and Gospel, Justification and Sanctification, Faith and Sense, Heaven and Hell By the late Reverend Mr. Ralph Erskine, Minister of the Gospel at Dunfermline." My copy is the 25th Edition. Edinburgh, 1797 :-- a sufficient evidence of the popularity which this work once had.

witty poetic rival, Sir John Denham. The royalist—as the author of the ATHENE OXONIENSIS relates—owed a grudge to the captive poet, some of his family estates having gct into Wither's clutches. Nevertheless, he modestly prayed his Majesty not to hang him, for so long as Wither lived, he (Sir John Denham) would not be accounted the worst poet in England! Notwithstanding this slur on Wither's poetic repute, the song has evidently enjoyed great and enduring popularity, as is proved by numerous variations, and the gradual modernizing process it has gone through. The version of it which furnishes a text for the Rev. Ralph Erskine, betrays the touches of a modern hand; but in its general form it most nearly resembles the Broadside of 1672, with the antique flavour of which these "tobacco fumes" may fitly exhale their concluding whiff:

> The Indian weed, withered quite, Green at noon, cut down at night, Shews thy decay ; All flesh is hay, Thus think, then drink tobacco.

The pipe that is so lily white, Shows thee to be a mortal wight; Even as such, Gone at a touch, Thus think, then drink tobacco.

And when the smoke ascends on high, Think thou behold'st the vanity Of worldly stuff, Gone at a puff; Thus think, and drink tobacco.

And when the pipe grows foul within, Think on thy soul defiled with sin; And of the fire It doth require; Thus think, then drink tobacco.

The ashes that are left behind, May serve to put thee still in mind. That unto dust Return thou must; Thus think, then drink tobacco.

Most of the foregoing pages were already thrown off when the *Gateshead Observer*, of June 6th, 1857, reached me, with the following notice of proceedings at a meeting of the Society of Antiquaries

of Newcastle-on-Tyne. It may very fitly be appended as a note to this sketch, as sufficing to show the latest views of my friend, Dr. Bruce, on the antiquity of pipes and tobacco. It will be seen that he still speaks of the miniature Elfin pipes as *medieval*; but subsequent remarks seem to indicate that by this term he means the era of Queen Elizabeth, if not indeed that of the Revolution, though neither of them would be generally recognised as pertaining to the province of the medieval historian.

# "A PAPER-OF TOBACCO."

"Dr. Bruce said, when the circular convening the meeting was issued, there was no paper in prospect, and he had therefore written a short one, not anticipating the many interesting communications which had filled up the meeting so agreeably. His paper was on the subject of the clay-pipes occasionally found in situations where we should only expect to find remains of a time long anterior to that of Sir Walter Raleigh. To this subject his attention had been turned, within the last few days, by a letter received by the Treasurer (Mr. Fenwick) from a mutual friend-Dr. Daniel Wilson, of Toronto. The Doctor wrote ,--- 'What says Dr Bruce to the Roman tobacco-pipes now? Tell him I have got a crow to pluck with him for that. I get quoted from his pages, and held responsible for much more than I ever thought, said, or meant to say. Let him look-out for a missive from the land of tobacco.' The passage referred to, in his (Dr. Bruce's) second edition of 'The Roman Wall,' had, curiously enough, and vexatiously enough, been more quoted and translated, perhaps, than any other. It asked if smoking pipes must be numbered among Roman remains-such pipes, (some of the ordinary size, others of pigmy dimensions, with intermediate sizes,) having been found in Roman stations, in close association with remains of undoubted Roman origin. Dr. Wilson was quoted on the subject, where, in his Archæology of Scotland, he speaks of "Celtic," "Elfin," or "Danes" pipes, occasionally found under circumstances raising the supposition that tobacco was only introduced as a superior substitute for older narcotics. Dr. Bruce produced several specimens-one, a tiny bowl, dug from a depth of ten feet, in 1854, at the back of the Assembly Rooms of Newcastle, where, when a sewer under the Vicarage House was in course of construction, he was on the look-out for remains of the Roman Wall. In the Antwerp Museum, such pipes are exhibited as Roman antiquities; and some were found near the foundations of the Wall of Roman London, when laid bare in 1853. Still, to Dr. Wilson's Transatlantic inquiry: ' What says he to the Roman tobacco pipes now ?' he had to reply, that he feared they were but medieval, and, moreover, of a late date. He would briefly state the grounds of this conclusion : - 1. They were only met with, here and there, in connection with Roman remains; while in every Roman station, all the kinds of pottery used by the Romans were invariably found .--- 2. No traces of the practice of smoking presented themselves in classic authors.--3. Ancient herbals contained no notice of any vegetable used for smoking with pipes.-4. These old pipes, laid together, exhibited a regular gradation in size, from the fairy bowl to the pipe of the present day .-- 5. Elfin pipes were found some few years ago at Hoylake, in Cheshire, on the site where the troops of William III. were encamped previous to their embarkation for Ireland; on the battle-field of Boyne, at Dundalk, and in other parts of Ireland where William's

#### CANADIAN ENGLISH.

troops were quartered. 'With respect,' said one of his (Dr. Bruce's) reviewers, 'to the little tobacco pipe bowls, we may observe that their comparatively diminutive size may be well explained by the fact that, in the time of Queen Elizabeth tobacco was sold at five guineas the ounce, and that, in aftertimes, those who indulged in the expensive luxury of smoking tobacco, were accustomed, in buying it, to throw five shilling pieces into the opposite scale.' He (Dr. Bruce) feared, then, that the Elfin pipes—the Fairy pipes—the Danes' pipes—must be placed in the same category with—' Severus' Wall !'

"At the conclusion of the paper, Mr. E. Spoor stated that he had seen turned up, in building operations, hundreds of pipes together, smaller than any of those on the table, near the town walls of Newcastle."

From this it appears that the learned author of "THE ROMAN WALL," no longer accords to his mural Legionary the luxury of a pipe; and the defence of this venerable classic institution must be resigned to the more chivalrous archaeologists of the Continent, and especially to the Antiquaries of Antwerp, where Elfin tobacco-pipes are still exhibited as Roman relics; and among whom, we trust, still survives some collateral descendant of the venerable and praiseworthy Aldobrand Oldenbuck, the happy progenitor of the Laird of Monkbarns !

## CANADIAN ENGLISH.

BY THE REV. A. CONSTABLE GEIKIE.

## Read before the Canadian Institute, 28th March, 1857.

It is a growing opinion that the English tongue is destined to become, for many purposes at least, the language of the world. But supposing such an extension of our vernacular to be probable, will the world speak "English undefiled," or English very defiled indeed? I know nothing of the tendencies in Australia, New Zealand, or at the Cape; but certainly, the English we often hear spoken, and see written, in the United States and Canada, is by no means an improvement on the original. That the American retains some obsolete words, or uses current words in obsolete ways, cannot fairly be objected to, though the very same reasons justify the language of modern Quakerism. But this process will account for a small fraction of the pecularities of his language. He is daily inventing

words which are neither English in character, nor needed to supply any deficiency in the language; and even where peculiar circumstances may make such a coinage, or such perversion of words from their primary significance pardonable, the circumstances are continually disregarded, and they are applied in cases where no such need exists, to the exclusion of the proper phrase, and to the injury of the language.

Canada inevitably partakes of the same influences. Her language is largely affected by such lawless and vulgar innovations. New words are coined for ourselves by a process similar to that which calls them into being in the neighbouring States; still more, they are imported by travellers, daily circulated by American newspapers, and eagerly incorporated into the language of our Provincial press. The result is that, with that alacrity at sinking which belong to human nature, we are in a fair way of appropriating what is worthless in the word coinage of our neighbours, in addition to all which our peculiar position may generate among ourselves.

It is not necessary to attempt any methodic classification of words or phrases; the purpose of this paper will be sufficiently accomplished by noticing a few of the most characteristic novelties as they occur to me. Neither shall I make any distinction between obsolete words and modern inventions. It is enough if it can be shown that words, unrecognized by good authors, are daily used; that words duly recognized are used in improper ways; or that extraordinary creations, and combinations of letters and phrases, are extensively circulated without supplying a recognized want, or contributing in any sense to the enrichment of the language. To refer, then, to a few examples of such transatlantic innovations on the English language : when Englishmen wish to mark their sense of the services of some public personage, by a suitable testimonial, they are said to give or present something to him, and the thing so given or presented is called a gift or present. But with us it is becoming fashionable to speak of such a gift as a *donation*, and still more of a thing *donated*. A minister is, with peculiar delicacy, dragged up before two or three hundred people and a band of music, to receive a present from his congregation, of a horse, it may be, or a purse of money,-and this gift, dubbed a donation, is donated to him at what is called a donation-meeting. Webster says, that *donation* is usually applied to things of more value than presents; but while such may be true in the States, I have known it applied here to a basket of musty cakes. I suppose that donation, has a certain meaning in law. Its most ordinary English application is to a single gift in money, in contra-distinction to the periodical

payments of a fixed sum as subscription. When applied to a *present*, public or private, I apprehend such an application of the term has its origin in mere pomposity. The language stands in need of no such expression so long as we have our old Saxon *gift*.

In England, when one man accommodates another with the use of money for a time, he lends it. The sum is called a *loan*, but he who provides it is said to *lend* or to have *lent*. Here, however, it is becoming usual to speak of having *loaned* to another. Webster says that to *loan* is rarely used in England, and I may say that I never heard it there. What advantage then does it possess over the more familiar form of the verb that it should supersede it here? Surely the phrase "money to lend," is sufficiently intelligible. To talk of *loaning* money, would suggest to an unsophisticated Englishman, the idea of some unknown process at the mint.

Again, let a clergyman study his sermon, a professor his lecture, a member of Parliament his speech, or a merchant the state of the markets and the rate of exchange : an educated or uneducated Englishman would probably say, "the man is master of his subject," and than this, more need not and cannot be said. In the States and Canada, however, a new phrase is current. A member of our Assembly makes a luminious speech, say about that great institution of modern civilization, the gallows,-and writers forthwith remark, that "he is posted-up on it." A Professor of Anatomy gives a lecture on some abtruse branch of his department of medical education, and his admiring pupils exclaim that "he is well posted-up on his subject." A metaphysician once more grapples with the old problem how many angels can stand on the point of a needle, and he, too is posted-up on it." A clergyman is posted-up in theology, a blacksmith in iron, a milliner in crinoline, a mother in nursery government, and an undertaker in the art of "performing" funerals, and coffining his customers. But, while ledgers may and should be " posted," it has not hitherto been the English practise to treat men so, unless they be black-legs.

A man in England possesses notable capacity, and people style him capable, or able, or great. In Canada he is designated first-class. To speak of a first-class carriage, or a first-class prize, or even a first-class prize ox, may be right enough, but why apply phrases with such poor associations to men of splendid intellect? Is it not enough that a man be great? Will he seem any greater when indissolubly associated with a railway van? The originators of such expressions no doubt thought so, but if the victim of such a nick name be what it is supposed to imply, he will not thank his admirers for the compliment.

A man in Britain buys a house, or farm, and it is said to be *in*, or more precisely, *situated in* such a street, or district, or county. Here, nobody or thing is *situated* anywhere; all are *located*. Our farms, our houses, our congregations, our constituencies, all are *located*. We admire a mansion occupying a healthy, or commanding site, and we are told that "the *location* is good;" a clergyman is congratulated on his incumbency, which is styled a comfortable *location*; and so on *ad infinitum*. To *locate* is a purely technical term, belonging to land-surveyors and their profession, and it is difficult to perceive any gain to the language by its application being extended beyond its original technical significance.

Ask an Englishman how much he has accomplished of a given work, and he will reply if getting on well, "a good deal." Ask the same question in our own colony, and if in a like position, the answer will be, "considerable." Now, considerable means, "worthy of consideration." Thus: "a man has a considerable fortune." We can understand when, in answer to the question, "how are you getting on with your mathematics?" the student replies considerable, or, still more elegantly, "considerable much." He means to say, "very well" and it is to be regreted that he should not say so. Or to give another specimen of the novel mode of applying this word considerable ; a newspaper editor recently illustrating by comparison the telegraph-cable designed to unite Canada with the States, by being laid in the bed of the River St. Clair, from Detroit to the Canadian shore, says of it : "it is larger by considerable than the Atlantic submarine cable."

A man concludes a bargain, and he resolves on a certain course of action. A man also comes to a conclusion after having considered a matter. But there is a difference between coming to a conclusion and resolving. To do the former, merely implies that he has formed an opinion, to do the latter implies that he has determined on a course of action. So we understand it, and so the words are used in English literature. But it is becoming common in Canada to confound conclude and resolve, and to speak of conclusions when resolutions are intended. Thus:—" I conclude to go," is put for, "I have resolved or made up my mind to go ;" surely a very needless confusion of ideas or vocables.

A territory is defined by Webster to be "a tract of land belonging. to, or under the dominion of a prince or state, lying at a distance from the parent country, or from the seat of government." It is also used for the *whole lands* belonging to any kingdom or state. On

#### CANADIAN ENGLISH.

this continent, it is often applied in its first signification, thus :--" the territory of Wisconsin," and indicates then, either all the lands of a state or nation, or certain distant or outlying possessions. Region and district again indicate a portion only of a kingdom, province, or territory. But a district may indicate a very minute portion of a state, county, or even of a city; whereas a region describes so wide an extent of country, as almost to be synonymous with that word. Beginning, then, with the latter, we say district means the smallest measure, territory a large measure, and region the largest of all. But in the States and Canada, the three words are often confounded; territory is put for region, and region for district, until neither word has any exact or specific meaning left. It is inevitable, indeed, in a new country, settled under peculiar circumstances, so different from those of the mother country, that new terms should be devised. Hence our Gores, Townships, Concessions, broken-fronts, water-lots, &c. But all of these are definite, universally understood with the same significance, and so contribute to the precision of language, instead of detracting from it, and as such, some of them at least, will be permanently incorporated into the English language.

People who speak English, say of a jury when it returns to court, and expresses its judgment, that "it renders its verdict," and this act is called "the rendering of a verdict," or technically "its finding." All this appears intelligible, and we are slow to imagine anything plainer. But people who, whatever their shortcomings, try to speak the language of Swift and Addison, are little aware of the progress of the age. With many among us, juries never render verdicts, but make rendition of them; and such, in lieu of speaking of a finding or rendering, refer to what they style a rendition, a mode of expression which, whatever it may be, is not English in such a connection. There is such a word as rendition, but it means surrender or yielding possession. it is a diplomatic, or law term, more than anything else. Let us apply the true meaning of the word to the action of a jury. Thus :---" the jury returned to court in the course of half-an-hour, and surrendered or yielded possession of their verdict." I submit that such bodies of men give, or express, but do not surrender opinions. Indeed, one would like to know how any man could surrender an opinion? A man may make rendition of his property, but he only expresses his sentiments. As the men of Derry said, so say I, "no surrender." But the most absurd use of this abused word may be illustrated by its mode of introduction in a newspaper notice of a concert recently given in Toronto.

The writer seems to have been pleased with some tune, and he accordingly speaks of "the beauty of its *rendition*." Musical people do speak in a certain sense of "*rendering* tunes," but the author of this critique has the honour of originating the idea of a tune being capable of *rendition*. The unsophisticated reader would be sorely tempted to ask how in all the world could a man *surrender* a tune? Doing so implies a measure of coercion. But can a singer be forced to sing, or even, having done so, does he thereby surrender the tune? By force you may take the notes out of his hand, but how can you take them out of his throat?

In England it occasionally happens that great offenders are hanged, but in the States and Canada, criminals are never hanged; they are all hung. In England, beef is hung, gates are hung, and curtains are hung, but felons are hanged; in Canada, felons, beef, gates, and curtains, are all treated in the same way.

But our English is not only wayward and independent, it is also so exceedingly modest, that we are in danger, not only of altering our vernacular, but of forgetting how our bodies are constructed. If we know anything of English conversation or letters, we speedily find out, even if stone-blind, that British men and women have both arms and legs. But in Canada, a stranger who could not see, would find it difficult to discover much about our conformation. He would learn that both sexes had'*limbs* of some sort, but from any information which our language would give, he could not tell whether their *limbs* were used to stand on or hold by.

Among British domestic fowls there are many styled gallinaceous: and among these are cocks and hens, male and female. But a blind naturalist could never fancy that we have the same distinctions in Canada. He would, indeed learn that we have hens ; but he would wonder in vain what had become of their mates. That there existed an unknown creature called a rooster, he would early discover, but unless he made particular enquiry, he might return after a year's residence among us, thoroughly convinced that there were no cocks in the province. Still greater, perhaps, would be his surprise, on making the discovery, to learn that in using the old familiar English name for the hero of the barn-yard, he had been using a very immodest word. This sort of thing is preeminently disgusting, and speaks ill, not merely for the taste, but for the morals of those with whom such a refinement originated. In Canada, such a garment as trowsers is unknown. What do we wear? Pantaloons is the reply; or more familiarly pants, with the feminine elegancy pantalets !

But is this the fact? Certainly it is not. At least it has never been my fortune to meet with one in this country who wore them. Pantaloons are an article of dress, out of fashion for fifty years. In more familiar vernacular they were wont to be called skin-tights, and while answering a similar purpose, are very different from trowsers in their shape. The origin of such a misnomer is sufficiently obvious. Such prudish euphemisms are by no means peculiar to Canada or the States. They find their complete parallel in the English synonymes : *unmentionables* or *inexpressibles*, and the like familiar shiboleths of immodest prudery, which belong exclusively to no class or county, but are none the less to be avoided by all who would regulate their mode of thought and expression by purity and true refinement.

In England, good housewives and the lieges at large, are sometimes horrified by the apparition of a loathsome insect, yclept a bug. Gardeners also find creatures of the same genus on their plants, and zoologists are familiar with numerous varieties of them. But, however great the variety, and however diverse the habits of different species, few words associated with insect life are so universally avoided, or are, from certain associations, more revolting than this monosyllable. And yet, we hear people on this side of the Atlantic. who, to say the least of it, are quite as familiar with this insect-pest as those on the other, -- applying this nauseous title to the beautiful firefly which makes our fields so glorious on a warm summer night. Canadians call it the "lightning-bug !" Here, we have, not simply an abuse of language, but a breach of good taste, which it might be thought no person of refinement could ever perpetrate As well might they dignify a vase of sweetly scented roses by making it share with the offensive and suffocating missile occasionally employed in naval warfare, the euphonious epithet of "stink-pot!" Moreover as this term bug is universally employed both in Canada and the States as a synonym for *insect*, the further result is a loss of precision. such as, in the commonest use of terms at home, discriminates at once between a fly, a beetle, and a grub. In England the term fly is also applied occasionally to a light vehicle, and it is on the same principle I presume that a four wheeled gig receives here the elegant name of buggy !

Turning again to another class of words; there is a curious disposition manifested among our manufacturers of improved English, to convert our regular into irregular verbs, for the sake of gaining what some modern grammarians have styled the strong preterite. In England, when a swimmer makes his first leap, head foremost, into the water he is said to *dive*, and is spoken of as having *dived*, in accordance with the ordinary and regular construction of the verb. Not so however, is it with the modern refinements of our Canadian English. In referring to such a feat here, it would be said, not that he *dived*, but that he *dove*. Even Longfellow makes use of this form,—so harsh and unfamiliar to English ears,—in the musical measures of his "Hiawatha :—

> "Straight into the river Kwasind Plunged as if he were an otter, *Dove* as if he were a beaver," &c.

As we say drive, drove, driven, we may look for the completion of the verb to dive, on its new model, and find the next poet's hero having "diven as if he were a beaver" or any other amphibious native of the new world. Though as yet unsanctioned by such classic authority, the verb to give not unfrequently assumes among us the past form of he guv, rose becomes ris, chid—chode, delved—do/ve, helped —holp, or holped, swelled—swell, &c. Yet so lawless and systemless are the changes, that, along with such alterations, which might seem to aim at a universal creation of strong preterites, we have the process reversed, and froze becomes freezed or friz, felt-feeled, &c. That some of these are as yet mere vulgarisms is not to be denied, but when the older examples receive the sanction of the highest literary authorities we may reasonably dread that the adoption of the remainder is a mere question of time.

When an Englishman speaks at random or without sufficient authority, he quesses. When he expresses an opinion, he thinks. Guess and think are not synonymes, but refer to two opposite states of mind. Far otherwise is it in the neighbouring republic, and with too many here; for, with Americans and their imitators, quess and think have an identical signification. A "Clear-grit" quesses that the person beside him who does not spit on the floor, is a tory and a contemptible aristocrat, while a tobacco-moistening "Hoosier" quesses, and for like reasons, that a Boston merchant must be a federalist. Now if they only knew it, neither of these discerning and refined individuals quesses at all. Contrariwise. each feels confident in the matter pronounced upon. The general conduct of the persons of whom they thus judge, together with the subdued action of their salivary glands, has satisfied both that the political tendencies of the others must be the antithesis of their own. They are in no uncertainty, and a quess is impossible. The ordinary American use of this word justly

subjects its users to ridicule, unless the precision which our English tongue once boasted of is no longer a feature worth preserving.

But a volume might be written about the evils glanced at here. In closing this paper, therefore, I can only indicate a few more of the indigenous elegancies which are already meeting with such general acceptance, and thereby corrupting, not simply the speech of the Province, but such literature as we have. It cannot, we fear, be justly affirmed that such expressions as the following are so entirely confined to the vulgar and uneducated as to be undeserving of notice as an element likely to affect permanently the language of the Province :—

"Are you better to-day?" inquires Britannicus. "Some," replies Canadiensis. "Were there many people present ?" asks B. "quite a number," answers C, meaning thereby "a number," for how can a number be otherwise than quite a number? B:- "Where did you go to-day ?" C:-- " down town," that is, he walked through, or in the city. B:--" are you going by this train ?" C:-" yes, I'm just on board." B :-- " where is your master ?" C :-- " the boss is out." B :-- "How many horses have you ?" C :-- " a span," which word he substitutes for "a pair." B:-" what is that man's character ?" C:- "he's a loafer," that is, in plain English, "a good for nothing fellow." B :-- " how do you vote ?" C :-- " I go the Hincks ticket." B:- "has there been a committee meeting?" C:- "yes, they had a caucus last night." B:--" can that wheel revolve now ?" C:--"ves, I guess it can do nothing else, for I've fixed it." B:--"did you mend my shoe." C :-- " yes, I've fixed it." B :-- " when will your sister be ready ?" C:-Jane is just *fixing* her hair." B:-"what do you eat to venison?" C := "jelly *fixings*." B := "what have you done with your other horse ?" C := "I've *dickered* him." B:--" what kind of a speaker is W-?" C:-" a stump-orator." B: -" how did he get his present office ?" C:-" by chiselling." B: -" is there much jobbing in the house ?" C:-" no end of logrolling." B :-- "did he run away ?" C :-- "yes, he sloped," or "he made tracks." B:--" how do you feel to-day ?" C:--I'm quite sick." B:--" sick ! why don't you take something to settle your stomach ?" C:-- "my stomach isn't unsettled. Its my toe that aches !" &c.

Nor is it in solitary words or phrases alone that we are thus aiming at "gilding refined gold," in our improvements on the English language. So far has this process already been carried that it would not be difficult to construct whole sentences of our Canadian vernacular which, to the home-bred ear, would stand nearly as much in need of translation, as an oration of one of the Huron or Chippeway Chiefs whom we have supplanted from their ancient hunting grounds on the shores of the great lakes. Let us take a brief example. A Canadian who has enjoyed the advantages of the American vocabulary will thus describe a very simple transaction :--" I traded my last yorker for a plug of honey dew, and got plaguy chiseled by a loafer whose boss had dickered his lot and betterments for notions to his store ;" some of the words introduced here are genuine Americanisms, such as *betterments*, *i.e.* improvements on new lands : lot, or division of land; town lots, sites within the area designed for a village or town; boss (Dutch) the euphemism for the unpalatable word master; and store, the invariably term for a shop. Others again, such as yorker: a shilling york currency, or sixpence sterling, are no less genuinely Canadian; and the whole, will become intelligible for the first time to the inexperienced English ear when thus translated :--"I exchanged my last sixpence for a packet of tobacco, and got thoroughly cheated by a disreputable fellow whose employer had bartered a piece of improved land to obtain small wares for his shop."

These and a thousand other examples which might be produced. fully justify the use of the term " Canadian English," as expressive of a corrupt dialect growing up amongst our population, and gradually finding access to our periodical literature, until it threatens to produce a language as unlike our noble mother tongue as the negro patua, or the Chinese pidgeon English. That the English language is still open to additions no one can doubt, or that it assimilates to itself, when needful, even the racy vernacular of to-day, to enrich itself, where synonymes are wanting. Hence, whenever a single word supplies the place of what could only be formerly expressed by a sentence, - unless the word be singularily uneuphoneous,-the language gains by its adoption. But if *chiseling* only means *cheating* : and log-rolling, -jobbing; and clearing out, or making tracks, -running away; then most men of taste will have little hesitation in their choice between the oldfashioned English of Shakespeare, Milton. Swift, and Addison, and such modern enrichments of the old "well of English undefiled." Such words-of-all-work, again, as some, and quite, and fix, and guess, having already a precise and recognized acceptance in classical English, it is probable that good writers and educated speakers will still recognize them in such sense, and when they fix a wheel immovably, they will say they have fixed it; but

VOL. II.-Y

when they mend or repair the same wheel, they will find no inconvenience in using one of the latter terms as equally apt and less ambiguous. And so also when they make a *guess* at some fact beyond their certain knowledge they will say so; but when they speak of what they actually do know, they will state it as a fact, and not guess about it.

An amusing illustration of the manner in which such misuse of words can obscure the sense of their true meaning even in the minds of educated men, is furnished by a critical comment in the "Shakespear's Scholar," of Richard Grant White, A.M.,\* on the following passage in "Richard III." Act IV, Scene IV:-

> STANLEY. Richmond is on the seas. K. RICHARD. There let him sink—and be the seas on him. White livered runnagate ;—what doth he there ? STANLEY. I know not, mighty sovereign, but by guess. K. RICHARD. Well, as you guess?

A better illustration of the correct use of the word could no where be found. Stanley says he does not know, he only guesses; and the king replies; well tell me what your guess or suspicion is. But hear the American critic:—" If there be two words for the use of which, more than any others, our English cousins twit us, they are 'well,' as an interrogative exclamation, and 'guess.' Milton uses both, as Shakespear also frequently does, and exactly in the way in which they are used in America; and here we have them both in half a line. Like most of those words and phrases which it pleases John Bull to call Americanisms, they are English of the purest and best, which have lived here while they have died out in the mother country." To such "*English of the purest and best!*" are we fast hastening, if some check is not put on the present tendencies of our colloquial speech, and the style adopted in our periodical literature.

It may be assumed that enough has now been said to shew the truth of the complaint with which this paper began. How then is the evil to be remedied? One or two suggestions occur to me which may not seem unworthy of some attention, as means calculated to check in some degree this growing evil. The first is that, educated men in private stations should carefully guard against the errors indicated, and others germane to them, and use their influence to check them when introduced. The second is, that our common school teachers should not only do likewise, but should correct the children under their care, whenever they utter slang or corrupt English, not

<sup>\*</sup> Shakespear's Scholar; being historical and critical studies of his text, characters and commentators, &c. By R. G. White, A.M. Appleton & Co., New York 1854.

only in the school, but in the play-ground, and on the streets; and the third is that, our newspaper and other writers should abstain from the attempt to add new force to the English tongue by improving the language of Shakespeare, Bacon, Dryden, and Addison. It is true that these are antiquated names; and it may be that some among us rather know them by the hearing of the ear than the sight of their works; still, weak though it may seem, and—to cull once more, for the sake of illustration, one of the choicest phrases of Canadian letters,—" old fogyish" though it may appear, I cannot get rid of the impression, that those men understood English fully as well as any American or Canadian author, and that, though they never wrote slang, no one either on this side of the Atlantic, or on the other, has written, or is likely to write, either with augmented force, or greater clearness.

# ON THE ORIGIN AND METAMORPHOSIS OF SOME SEDIMENTARY ROCKS.

# BY T. STERRY HUNT, OF THE GEOLOGICAL SURVEY OF CANADA.

The progress of Geological investigation has shown that many masses formerly regarded as primitive and even as hypogene rocks, belong to formations, which in other parts of their geographical distribution appear in the form of sedimentary strata, destitute of crystalline character, and distinguished by their organic remains as pertaining to various geological epochs. Thus the researches of Sir William Logan have shown conclusively that the serpentines, talcs, diallages and pyroxenites of the Green Mountains are portions of altered Silurian Strata, and I have already suggested that these rocks have been formed by the metamorphosis of certain beds of silicious and *ferruginous* dolomites and magnesites which occur in the Quebec division of the Hudson River Group, and are found in its unaltered portions interstratified with pure fossiliferous limestones, sandstones, and graptolitic shales.

Dolomites have, until recently, been regarded for the most part as altered rocks, and the mode of their formation is but little understood. When carbonated waters, containing lime and magnesia in solution, are

exposed to the air, the former base alone is at first deposited, and the magnesian carbonate is only separated by evaporation. When carbonate of soda is added in small quantities to a liquid, such as sea water, containing chlorides of these two bases, the precipitate formed in the cold consists chiefly of carbonate of lime, and the liquid, by evaporaration, deposits a large quantity of carbonate of magnesia with a little lime, and then contains only chloride of magnesia (with soda salts) in solution. It is well known that the precipitate formed by carbonate of soda in a solution of chloride of magnesium is soluble in an excess of either of these salts. We have in Canada a great number of saline springs, which rise from Lower Silurian rocks, and appear to be formed by the mingling of the bittern-like waters, destitute of earthy carbonates, and derived from the lower limestones, with the carbonated alkaline waters of some of the associated strata. These saline springs, such as Plantagenet, St. Léon, and Sainte-Geneviève, deposit by evaporation, at a gentle heat, large quantities of earthy carbonates, of which the carbonate of magnesia forms from 50 to 95 per cent.; they sometimes contain but a trace of carbonate of lime. The spontaneous evaporation of basins of similar waters would give rise to the formation of dolomites or magnesites which would assume the form of detached or interrupted beds or lenticular masses among the pure limestones and other non-magnesian deposits of the region. Such are precisely the conditions in which the magnesian rocks occur in the Hudson River Group. Many of them may, however, be the result of a direct precipitation which may take place in deep sea water, from the infusion of alkaline carbonates.

Mingled as these magnesian deposits naturally are with sand and clay, we have in the silica, magnesia, lime, alumina, and oxide of iron of the sediment, the elements of serpentine, talc, pyroxene, hornblende and chlorite. For the production of these minerals it is necessary to dissolve the silica, and cause it to unite with the bases present, expelling the carbonic acid. The agent in this reaction has doubtless been an alkali. A solution of carbonate of soda at 212° F. will slowly dissolve silica, even in the form of quartz, and the silicate of soda thus formed, is at once decomposed at this temperature by the carbonates of lime, magnesia, or iron, with the production of a silicate of these bases, and the regeneration of the alkaline carbonate, which is then free to operate upon a new portion of silica. In this way a small amount of alkali may serve as the medium for the silicification of a large amount of carbonates. I have verified all these reactions by experiment, and have found that a silicate of magnesia is formed when quartz is boiled with carbonate of magnesia, and a solution of carbonate of soda.

A silicate of protoxide of iron, unalterable in the air, may be formed by an analogous process. The reactions of alumina, and of silicate of alumina under similar conditions have yet to be examined.

It appears to me that by this extension which I have given to the reaction between carbonate of lime and soluble glass, already pointed out by Kuhlmann, we have a key to the mode of formation of most of the silicates of the metamorphic stratified rocks. The subject will be found still farther developed in the forthcoming Report of Progress of the Geological Survey.

# NOTES ON THE NATURAL HISTORY OF NEW ZEALAND.

## BY S. P. STRATFORD, M.D., OF AUCKLAND, NEW ZEALAND.

Read before the Canadian Institute, 28th February, 1857.

Having been fortunate enough to secure a favorable opportunity for transmitting a package to Canada, I have availed myself of it to forward, for the Museum of the Canadian Institute, some specimens of the geological formations and objects of natural history belonging to this part of the world, which I hope may possess some interest for the members of the Institute.

Among the geological specimens will be found vesicular scoriæ, lava, volcanic ashes and cinders. These abound in almost all parts of New Zealand, and in the neighbourhood of Auckland are particularly marked. Auckland, indeed, is a spot especially favorable to the study of volcanic action, and I only regret that professional engagements prevent my paying such attention to the subject as I would wish. It may not, however, prove unacceptable, if I accompany the specimens with a few remarks upon the subject, or at least note, for my Canadian friends, some facts connected with the traces of volcanic action in this neighbourhood.

In the immediate vicinity of Auckland we have volcanic cones of various dimensions, from the height of a few feet to upwards of one thousand feet. They are grouped together in clusters, so that from the top of Mount Eden, two miles from this city, eighteen or twenty may be counted. It must not, however, be imagined, that the vol-

#### NATURAL HISTORY

canoes in the immediate vicinity of Auckland are the highest. Tongeraro, an active volcano in the centre of the island, is extremely high, rising far above the level of the perpetual snow line. It is in almost continual action, and is surrounded by mountains with altitudes approaching its own, and which exhibit clear indications of a volcanic origin; indeed, the whole country shows that the volcanic influence is general, and I imagine that the incandescent material approaches the earth's surface in an unusual manner. Solfataras, or volcanic vents, are met with, and accompanying these, abundant exudations of sulphur, of nitrate of potash. &c. Hot springs and mineral waters abound; indeed, the hot springs of Rotumakana, at which the natives cook their food, and which, from their volume, are more like cataracts than springs, fall into Lake Tampo, and heat the waters of the lake for a considerable distance around. I do not doubt that these remarkable springs will hereafter become objects of no slight interest to the geologist.

Sulphur springs are numerous, and an efflorescence of sulphate of alumina is found spreading over extensive surfaces of the earth, while the volcanic fire, which I imagine to be the remains of an enormous lava current not vet cooled, is so near the surface that a red heat may be seen in the interior, through openings in the earth ; indeed, it is said that the crust sometimes breaks through, and exposes a considerable extent of burning matter. Sometimes bogs or swamps of boiling water are met with, covered by a thin crust of earth. A short time since a Missionary travelling in this volcanic region of New Zealand, ventured to cross such a surface. He broke through into the scalding water, and had his extremities dreadfully injured. It would take a long time to investigate all that is novel and interesting in this part of the country, as it is covered by an interminable forest of great density, such as a tropical climate could alone equal. It is characterised by dense vegetation, and with an immense number of climbers and vegetable parasites of great and varied luxuriance.

Auckland is distant some 500 or 600 miles from the mountain region of New Zealand; and as I have not yet penetrated to that elevated district, I cannot speak of it from personal observation. But as the Waikatu river, which rises in Lake Tampo, takes a northerly direction for 300 miles, emptying itself into the sea on the west coast of the Island, and as settlements have already been commenced along its shores, which are in direct connection with Auckland, the time is not far distant when a visit to the highlands of New Zealand will be

mainly included in a pleasure trip up the Waikatu river in a steamer. The whole valley of the Waikatu is of the most luxuriant description, abounding in excellent pasture lands; admirably adapted for grazing, and holding out many inducements to the agricultural settler.

As I have before mentioned, some eighteen or twenty volcanic cones or craters of eruption may be counted within a few miles of Auckland. Taking Mount Eden as an example; it is about 800 feet high, with a crater 300 feet deep and from 400 to 500 feet wide. The upper part consists of very light ashes, its lip is very uneven, while hillocks of ashes may be seen at different points around it. The unevenness of the lip of the crater would seem to be caused by the influence of the wind, the deposits occurring on the points towards which the wind generally blows. In some instances it would appear to depend on the sudden cooling and falling in of the lava current, as I find that the depression of the lip is often immediately over the direction which the lava took when it forced its way through the sides of the crater.

Judging solely by their external appearance, some of these cones appear to be only mounds of volcanic ashes, being flat or nearly so on the surface, but as they are distant from any other rent, and surrounded by lava and other indications of volcanic action, their true origin cannot be doubted. In some cases the craters are filled with water, forming beautiful little lakes.

I find that the lava currents of Mount Eden have taken for the most part a N. E. or N. W. direction ; when they forced their way through the ashes they ran down the sides and spread themselves over the country, leaving at these spots a marked depression of the crater lip. I think I can distinguish several distinct layers of lava, and one has evidently preceded the other by a considerable period; thus the hard stony matter may be observed to have exuded in a certain direction, ending in some instances in a rounded surface, in a manner that -- to use a homely simile-reminds one of hasty pud. ding which has almost ceased to run; a surface that has begun to cool and solidify, but is yet pushed forward by the fluid beneath. The more general appearance of the lava currents, however, is a surface broken up, cracked and split in all directions, the leaves are extremeuneven, and we find rugged surfaces of rock piled on each other in extreme confusion. The lavas about Mount Eden are of a blueish gray colour like trap, as will be observed in a specimen which I have sent. At the extremity of the lava current there is generally

#### NATURAL HISTORY

found a stream of water, in which most commonly splendid watercresses abound, along with many beautiful aquatic plants which remain green throughout the year. Among them may be mentioned the celebrated Rapo or *Typha augustifolia*, which is used by the natives and by new settlers as a convenient building material. They form the walls and roofs of their houses of bunches of it, and tie them together with the Mangi-mangi or climbing fern, *Lygedium articulatum*. Very warm and convenient houses are thus constructed, impervious to rain or wind. I have seen the inside lined with cotton, aud then covered with figured paper; and thus finished it is exceedingly comfortable, and makes a very respectable appearance.

The New Zealand flax, *Phormium tenax*, grows on the margins of the streams, its leaves often measuring six feet in height, surmounted by the flowers on an elevated foot stalk. Its dark green leaves and its tuft-like appearance render it a most graceful object. Again the observer will meet with a cluster of the New Zealand fern tree? *Cyathea medullaris*, the noble palm tree, *Areca sapida*, or the curious grass tree, surmounted by tall luxuriant ferns. These present a pleasant picture, a combination of grace and beauty not to be surpassed, I believe, in any other part of the world.

In the layers of volcanic matter I could easily count three successive streams of lava which are now piled one above the other in wild confusion. These eruptions tended towards the N.E. Towards the N. W. the expanse of erupted matter is more extended, rugged and broken, but does not appear to be the result of so many distinct volcanic actions. If the course of the lava current is traced, it sometimes appears to dip, or penetrate the earth for certain distances, again appearing upon the surface. In some instances a smooth dome like surface of the lava will be met with which has cooled without fracture. This presents unmistakeable evidence upon its surface of having flowed slowly, or cooled as it flowed, for marks like wrinkles may be observed, on percussion it sounds hollow, and it has plainly been a spot where the fluid lava was arrested for a short period and its surface cooled, while the internal fluid lava continued its course to the lower levels of the plain. At other points in the same current it may be observed that these domes have given way, and now form deep, rugged and dangerous cavities into which animals sometimes fall, and can seldom get out without assistance, although they may penetrate to some considerable distance along the course of the current. Some of these cavities contain water, and in many instances they are almost concealed by the thick foliage and beautiful evergreens which grow from them. In many examples where the lava current leaves the crater and passes into the open air, cavities of this description may be observed, and indeed the adventurous explorer may pass for miles underground along these *caves* as they are called. Most of such caves appear to have been the retreat of vanquished tribes, as human bones are often found in them in very great quantities.

At other points of the lava current, may be found as it were miniature volcanoes—points at which the lava current has been detained while still fluid, and where the confined gases have exploded with great violence, blowing up the lava as out of a crater, and spreading the matter in pieces over the surrounding surface. I conceive that the gases may have been produced, in part at least, by the decomposition of water which the lava met with in its course under the surface of the earth.

Around the mountain are to be found innumerable loose stones, some of enormous size, which have been ejected from the crater. These have often passed to a great distance, and are in some directions thickly covered with sand. A person unacquainted with this fact, would almost despair of being able to employ the land for agricultural purposes, but the stones are only on the surface, showing that the present soil existed before they were ejected. They are used for making permanent fences. Some of them consist of solid lava, others of vesicular scoriæ, most of them are round and appear to have assumed this shape from having been projected to a great height into the air while still in a fluid or semi-fluid condition.

The rough angular surface of the lava, which is fractured into deep chasms presenting abrupt angles, and looking to the eye as a chaotic mass, heaped up in wild confusion, instead of the even surface it presented while still liquid, is evidently owing to the changes of temperature which it has undergone, and the contraction of the particles consequent thereon. The enormous cracks and disjointed fractures are evidence of the intense heat which once pervaded the molten mass, and now make it difficult to believe that it ever presented an even surface.

I send you some of the earths which abound in the neighbourhood, convinced that they have all issued from the volcano in the form of mud or ashes, and as the constituents, and the peculiar condition of such may involve questions interesting to the geologist, I thought you would probably be pleased to receive them, and might cause them to be analysed. I am fully convinced that not one of the layers of earth which I find about Auckland and its neighbourhood is of sedimentary origin, and I believe a chemical analysis will clearly show this fact.

The peculiar shape and conformation of the land also tends to prove the same, the lay of the land generally indicates spurs or buttresses, which seem to start from the volcano, and extend as rays from a centre, the base of the ray is to the mountain, and it tapers off until it is lost, and in most instances it takes such a shape as might have been assumed by a thick fluid mass flowing down the hill.

The vast number of volcanic rents in this neighbourhood, which have all in their time poured cut liquid mud and fluid lava, serve to produce great confusion and complexity in the arrangement of these formations, but by care and perseverance we can generally trace the course of each current of mud. In some of them we find the round masses of vesicular scoria which have been incorporated in the mud and hurried down into the plain below.

In carefully analysing these avalanches of mud it is seen that each has its precise location according to the period of volcanic action. I believe that their difference depends in a great degree upon the depth from which the matter has come. If near the surface it possesses certain characters, but it changes as the combustion penetrates deeper into the central mass of the earth, and lastly fluid lava is forced out upon the surface. We are ignorant of many of the laws which regulate volcanic action, and I am certain that a noble field is open in this neighbourhood for that study, for we have rudimentary volcanoes in all stages of development until we arrive at Pongauro, which presents evidences of great age and continual activity.

The question which is naturally asked is, at what period were the volcanoes about Auckland in active operation. No reliable record has been preserved of that period by the inhabitants; the natives have a kind of tradition that Rangatoto, the highest of the volcanic vents about Auckland, was in operation during the last century; the name itself would seem to confirm this statement, as when translated it signifies "Blood-red sky," a common effect of the eruption of a volcano when seen by night. The discovery of lignite, evidently the remains of ferns and trees now growing in New Zealand, in all directions and under layers of great thickness, would lead to the conclusion that the process of formation had been recent; among the layers of earth I have sent, you will find lignite taken at a great depth, viz., from a well 50 feet deep. I was enabled easily to distinguish among the earth, fern roots and partially decomposed wood, besides which pieces of Kauri
gum were found, showing that not only had ferns grown there but also the noble pine—Dammara Australis. Although covered with a great volume of clay, these remains were enveloped in fine volcanic ashes, showing that such had preceded the eruption of mud. From another well equally deep, near the barracks, I have seen lignite brought up, but this was covered with volcanic cinders several feet thick, besides the clay I have before mentioned. Indeed all the evidence appears to be favorable to the idea of recent eruptions from these volcanic vents, and should it happen that several of them go into operation simultaneously, the inhabitants of Auckland will witness a terrific spectacle. In all probability full notice of the event will be given, in the form of earthquakes and subterranean noises, none of which have been noticed hitherto in sufficient intensity to excite any fear, at least during the last sixteen years.

I have mentioned that there are numerous pieces of rock lying about, but these are plainly scoriæ and derived from volcanoes in the immediate vicinity, not the water worn boulders seen so plentifully in Canada. Our latitude is about 36° south, but I have not seen any evidence of boulders conveyed by ice, and should their total absence be confirmed, I should regard it as a strong evidence of the recent formation of land in these parts.

In the strata formed in the Island of Rangatoto, and in various other parts of our neighbourhood, and which in some cases attain a considerable elevation, and have evidently been exposed to disturbing agencies, many shells and vegetable remains may be discovered. These shells are such as can be found on the shores at present in a living state, and the plants are such as still grow on the island.

These plants and shells have evidently been covered by eruptions of liquid mud or ashes. Cracks have been formed during the drying, and these are sometimes filled with carbonate or oxide of iron.

Such facts prove very clearly that the Islands of New Zealand are of quite a new formation, which is still further shown by the paucity in the variety of the vegetation, the almost total absence of animals, and the complete freedom from venomous reptiles. Although there are scarcely any native plants and animals, yet almost every species of plant and animal thrives well. The English pheasant and the guinea fowl has become wild, and the hogs left by Cook are now spread over the whole island.

The climate is most equable; during my twelve months residence, I have scarcely seen six really wet days, I have seen ice and the temperature has been as high as 75°, but these are the extremes, and occur very rarely. The natives are a fine race of men, and very apt at learning. They soon become good navigators; some own large schooners and sail them themselves; their cances are excellently made and will stand any sea. They own many mills and cultivate the land largely, the women doing most of the labor. Their character is kind and hospitable, and in war they are by no means to be despised. Their fortifications exhibit considerable ingenuity.

Among the specimens of natural curiosities will be found the vegetable caterpillar—the Spharia sicudes or Robertia as it is called. It is very abundant in New Zealand, especially upon the west coasts, where it is said that tons might be collected. I am in hopes it may become an article of trade with China, where the fungus is prized very highly and is used as a medicine. The Sphœria Robertia although bearing much resemblance to a caterpillar is evidently a plant, the mode of its production is said to depend upon the growth of a sporule of the fungus germinating within the body of the animal while yet alive. Aware of the disease, the caterpillar seeks the shelter of the Rata tree, and lays itself up to die under it, in due season the fungus shoots out its stem, flowers, seeds, and dies. From the specimen I have sent, abundant evidence of its fungus nature will be manifest. The butterfly that produces this caterpillar is said, by an intelligent friend from Hohinaga, to be the Hepialus Sericeus ; when the eggs are hatched, the caterpilar seeks the Kahikaton tree, bores into it to a great depth, and then covers its hole over with bark and web, so as to hide itself from the depredations of the Waita, a species of flea nearly as large as a mouse. I shall try my best to obtain correct information upon this matter with a view to communicate it to the Institute when I write again.

Along with the other specimens now forwarded, illustrative of the Natural History of New Zealand, I have sent a Hippocampus which was taken upon the little Barras island in the Gulph of Hourica, not far from Auckland.

## REVIEWS.

Catalogue of Human Crania in the Collection of the Academy of Natural Sciences of Philadelphia; based upon the third edition of Dr. Morton's "Catalogue of Skulls," &c. By J. Aitken Meigs, M.D., Librarian of the Academy of Natural Sciences of Philadelphia, &c. Philadelphia: J. B. Lippincott & Co., 1857.

No purely scientific American work has more firmly, though slowly, established its claims to a permanent place among the valued contribu-

tions to the materials of progressive science, in relation to some of the most important questions of our day, than the Crania Americana, the work of the late Dr. Samuel George Morton, of Philadelphia. Valuable, however, as it is, it cannot detract from the merit of its author's zealous and persevering labors to say, that it has furnished materials destined to lead others to still more comprehensive and exact results than any he arrived at. Nor did it complete his labors ; he was a worker until the last, and every production of his pen has a further value in relation to his chief contribution to ethnological science. Such is felt, in an especial manner, to be the case, in reference to the catalogue originally prepared by himself, and now carefully edited and enlarged so as to embrace the greatly augmented collection of skulls formed originally by its author. It furnishes many details, indispensable as addenda to the Crania Americana. Without it, for example, all the additional examples included in the "Table of Anatomical Measurements," in that work, are scarcely available for the general purposes of analysis and comparison. Of these it supplies, in relation to nearly all of them, the requisite facts as to sex, age, special characteristics, &c., most desirable to be ascertained. Had its careful and pains-taking editor, Dr. Meigs, added, in the case of those not included in the Crania Americana, some, at least, of the most essential measurements. such as the longitudinal, vertical and parietal diameters, and the horizontal circumference, he would have greatly increased its usefulness. In lieu of this he has followed Dr. Morton in giving the facial angle and the internal capacity of each; but to neither of these measurements can we attach much value. Beyond such aid as it gives in testing the prognathous character of the superior maxilla, the facial angle is valueless. It rarely takes into account the forehead, while it is liable to be greatly affected by comparatively insignificant variations in the maxilla and position of the teeth, and is so indefinite and uncertain that two accurate and experienced observers will frequently vary considerably in their measurements, executed with the same facial goniometer. So, also, the *internal capacity*, given as it is in this catalogue, without reference to the attempts made by Dr. Morton to discriminate between the comparative occipital, parietal, coronal, and frontal developments, can at most be available only for some general averages. In the great majority of the averages which Morton and later writers have struck, the number of examples is greatly too small; while, to do justice to the actual value of comparative cranial and cerebral capacity, the relative size of skull and skeleton must needs be ascertained. otherwise a small-headed and small-brained giant, with intellectual

powers considerably below the average, may compare advantageously in cerebral capacity with some Milton or Newton.

The Catalogue of Crania, as now edited by the intelligent librarian of the Academy of Natural Sciences of Philadelphia, is extensively illustrated with wood-cuts, executed for the various works to which it supplies an important supplement. In some respects it is expressly set forth in emendation of measurements and other data furnished in the Crania Americana; and for all facts in relation to the important cranial collection which supplied the materials for that great work, it is-as the latest authority, embodying the final corrections of its author, as well as the careful additions of the editor of this catalogue, -indispensable to the American ethnologist. The rapid progress which the Philadelphian collection of human crania is now making is shewn by the very discrepancies between the earlier and later sheets of the catalogue. On page 50 an addition of seven Esquimaux and two Loo Chooan skulls is recorded, the gift of Dr. B. Vreeland, U.S.N., who procured the former at Godhavn, Disco Island, on the coast of Greenland. Again, on page 102, the skull of an idiotic negress, of remarkable character, is noted as a still later addition; and the whole collection, at the date of the final correction of the catalogue, during the present summer, embraces a total of 1,045 human skulls, including specimens from so many localities, and selected with reference to such remarkable peculiarities of site, form, mode of sepulture, and the like, as to constitute it one of the most interesting and valuable series of ethnographic materials for study either in the New or the Old World.

D. W.

Progress of Mathematical and Physical Science. The Encyclopædia Britannica. Eighth edition. Dissertation Sixth: exhibiting a general view of the progress of Mathematics and Physical Science, principally from 1775 to 1850. By James David Forbes, D.C.L., F.R.S., Sec. R. S. E., Professor of Natural Philosophy in the University of Edinburgh, and Corresponding Member of the Institute of France. Edinburgh: Adam and Charles Black, 1856.

There are few undertakings which involve more formidable difficulties and require higher intellectual qualifications than the attempt to present, in a manner at once popularly intelligible and scientifically exact, the history of the progress of philosophy through any epoch.

For, in the first place, to write the history of any particular branch, the historian must have himself thoroughly mastered it; no mere dilettante or second-hand knowledge will save him from error on the one hand, or plagiarism on the other : however difficult or complicated the process by which an idea has been developed or result arrived at, it is essential that he go through it in all its details before he can venture to deviate from the form of words in which his predecessors or the author himself may have presented it. He is conscious also that his performance must bear the criticism of those who have made that department their especial study, and his knowledge is thus to be guaged by the standard, not of the average, but of the highest. When we consider the vast range and variety of direction, in which modern philosophy is sweeping, this requirement assumes alarming proportions, and, if to it we superadd the further difficulty of expressing scientific results in such language that he who runs may read-of stating in familiar words what is perhaps hard enough to understand in its proper technical form, we can hardly wonder that so few attempts have been made at thus writing the histories of even the separate physical sciences-much less that of the whole of them-and that scarcely any have been successful.

If the universal suffrage of the British scientific world had been taken, we believe it would have unanimously pointed out Professor Forbes of Edinburgh, as the man of all others (excepting only the illustrious author of the "History of the Inductive Sciences") most eminently fitted for the task, and the Dissertation, above cited, would have been a triumphant confirmation of their vote. Holding a prominent position in his University, and distinguished for original research in some special departments, Professor Forbes has been long known for one of the very few who have kept up their knowledge to the level of the general advance of philosophy throughout its whole extent, so far as may be done within the limits of human life and power. The work before us is in every respect worthy of his reputation, and we should find it hard to express our opinion of it in terms of praise which would not appear extravagant to persons whose perception of the excellence of the performance is not enhanced by a full appreciation of its difficulty. Regarding the work in its strictly scientific aspect, it becomes a reviewer to speak with diffidence, nor do we affect to be able to criticise all that is set down : we would only say, that in the departments with which we are most familiar, we have tracked our author minutely and rigorously, and that we have detected no inaccuracy of statement, no ambiguity of phrase by which a difficulty might be conveniently slurred over, none of those little slips which so often in "popular"

works enable the adept at once to say, "this man does not understand what he is writing :" all is exact, full, and genial as if the author enioved what he is describing; everywhere the subject is treated up to its very latest stage, nor have we noted a single omission of importance. On debatable points, whether of principle or history, its almost judicial clearness and impartiality are admirable, and even where we sometimes dissent from our author's opinion or decision, we have no fault to find with the manner of stating the case. In a literary point of view also, the work is excellently performed; the style is at once vigorous and elegant, reminding us of Herschel and Arago in their best efforts, and sometimes rising into eloquence as welcome as unexpected ; while for deep and exhaustive reflection, and acute and happy generalisation, it abounds in passages which make it on the whole one of the most instructive as well as delightful books we have ever read. We suppose we ought to feel shame in confessing to the hope that some dishonest publisher on this side the Atlantic will reproduce it as soon as possible, for although it is "supplied to subscribers gratis," that is small comfort to those whose pockets are not deep enough for that whole Encyclopædia Britannica, and whose inclinations are decided for having the pennyworth of bread without the sack.

The range of period over which this dissertation extends, is somewhat limited, including only the last preceding three quarters of a century; this selection having been determined, as Professor Forbes informs us, by the fact of the previous ground having been already occupied in the Encyclopædia by the dissertations of Playfair and Sir J. Leslie. We think this is a matter to be regretted, for we cannot endorse the laudation which Professor Forbes somewhat ostentatiously bestows on his predecessors' productions. That of Sir John Leslie is often inaccurate, not seldom unjust, and, viewed by the light of modern science, altogether incomplete : and if the same objections cannot be urged against that of Playfair, still it is encumbered by masses of heavy technicalities which he has attempted to popularise, but has only succeeded in rendering tedious for the savan and mostly unintelligible to the general reader. We sincerely wish that the publishers had cancelled these ineffective essays and induced Professor Forbes to re-write the history of that most important epoch which includes Galileo, Kepler and Newton. The following is the programme which Professor Forbes has set out to be performed, so condensed and yet so lucid that we have not the heart to abridge it, long as it is for our space.

I have adopted the period from about the year 1775 to 1850 as the general limit of my review. We may imagine this period, of three quarters of a century

preceding the present time, to be divided into three lesser intervals of 25 years each, which have also some peculiar features of their own.

From 1775 to 1800, many branches of science still continued in the comparatively inert state which characterised a great part of the eighteenth century. There were, however, two or three notable exceptions. One was the continued successful solution of the outstanding difficulties of the theory of gravity applied to the moon and planets, a task in which the continental mathematicians had no rivals or even coadjutors on this side of the channel; another was the foundation of sidereal astronomy; and the last was the commencement of a system of chemical philosophy based on new and important experiments, and including the laws of heat in combination with matter, which at that period very naturally ranged thémselves within the province of the chemist. I do not of course, mean to affirm that other branches of science were not cultivated with success within the exact period of which we speak. Electricity, for instance, first statical, afterwards that of the pile, had a share in the discoveries and speculations of the time. But these were rather the extension of what had been previously thought of, or the first dawn of future important results, whose development fills a large space in the succeeding story .....

The first quarter of the present century attained a higher and more universal celebrity. Scarcely a branch of physical science but received important and even capital additions. Physical astronomy indeed no longer filled so large a space in the page of discovery, simply because the exhaustive labors of the geometers of the former period had brought it to a stage of perfection nearly co-ordinate with the means of observation, and because, by the publication of the *Mccanique Celeste*, Laplace had rendered available and precise the masses of scattered research accumulated by the labors of a century since the close of Newton's career of discovery. It was in some sense a new book of "Principia,"—not, indeed, the work of one, but of many; nor of a few years, but of two generations at least. Still there it was, a great monument of successful toil, which, like its prototype, was for many years to be studied, even by minds of the highest order, rather than to be enlarged.

But the other branches of natural philosophy were now to make a stride, such as perhaps no preceding time had witnessed. The science of optics was speedily expanded almost two-fold, both in its facts and in its doctrines. Galvanic electricity disclosed a series of phenomena not less brilliant and unexpected in themselves, than important from the new light thus thrown on the still dawning science of chemistry, and from the power of the tool which they placed in the hands of philosophers. Before the first quarter of the present century closed, the important and long-suspected connection between electricity and magnetism was revealed, and its immediate consequences had been traced out with almost unparallelled ingenuity and expedition. The basis of the science of radiant heat, slightly anticipated by the philosophers of the eighteenth and even the seventeenth centuries, was finally laid in a distinct form, assigning to the agent, heat, an independent position dissociated from grosser matter, such as light had long enjoyed Astronomy, though enriched on the very first night of the new century by the discovery of a small planet, the herald of so many more of the same class, made perhaps less signal progress; but chemistry, besides the aid it received from the invention of the pile, had a triumph peculiarly its own in the addition of the comprehensive doctrine of definite-proportions, destined to throw at some later time a

VOL. II.-Z

stendy light on the vexed question of the constitution of matter. The great number of scientific names of the first order of merit concerned in these numerous discoveries marks the extraordinary fertility of the period......

Of the twenty-five years just elapsed, it is not so easy to speak with precision. The voice of criticism may be fairly uttered with that reserve which every one must feel in speaking of his immediate contemporaries. Yet it may perhaps be stated without just cause either of offence or regret, that it has not on the whole been characterised by the full maturity of so many commanding minds. Of the great discoverers of the former period, several survived and continued their efficient labors during no small portion of the latter ; and a few happily still remain to claim the respect and veneration of their disciples and successors. But the vast steps so recently made in optics, in electricity, in magnetism, in thermotics, and in chemical principles, tended of necessity to call forth such an amount of laborious detail in the defining and connecting of facts and laws, and the deduction of the theories started to explain them, as seemed to render fresh and striking originality somewhat hopeless, whilst they occasioned a vast amount of useful employment to minds of every order of talent. The undulatory theory of light, nobly blocked out by the massive labors of Young and Fresnel, has afforded still unexhausted material to the mathematician on the one hand, and to the experimentalist on the other; and ably have they fulfilled the double task, adding at the same time discoveries whose importance and difficulty would have made them still more prominent, had they not been the legitimate consequences of a still greater discovery already in our possession. Nearly the same might have been said for the sciences of electricity, electro-magnetism, and electro-chemistry, had not the comparative newness of the whole doctrine of these sciences, and the suddenness of their first rise, and, perhaps, still more, the appearance of a philosopher of the very highest merit, Mr. Faraday, who fortunately attached himself to this special department, made the last thirty years an almost unbroken period of discovery. Radiant heat, too, has been successfully advanced by labors comparable perhaps to those which marked its first rise as a science, and some other topics connected with heat have risen into great and practical consequence. Astronomy has been prosecuted with a systematic assiduity and success, especially at the British and Russian national observatories, which yields to that of no former period, whilst physical astronomy has been cultivated by methods of still improved analysis, and has achieved one triumph which France need not grudge to England, nor England to France,-so signal as to be placed by common consent in a position superior to any since the first publication of the theory of gravitation, more than a century and a half before. This was the prediction of the position in space of a planet whose existence was unknown except by the disturbance which it produced in the movements of another. Terrestrial magnetism has, for the first time, aspired to the rank of an exact science. In an illustrious philosopher of Germany, it has found its Kepler; and the combination of national efforts in collecting reliable data from the remotest corners of the globe is characteristic of the practical energy of the age. Pure chemistry has been cultivated with extraordinary assiduity; but though some general principles have emerged, none are comparable, from their importance, to the discovery of Dalton.....

It seems to me impossible to exclude from a review, however slight, of contemporary progress in the exact sciences, the advances which have accrued to them, both directly and, as it were, reflexively, by the astonishing progress of the me-

chanical arts. The causes, indeed, which called them forth are somewhat different from those which are active in more abstract, though scarcely more difficult studies. Increasing national wealth, numbers, and enterprise, are stimulants unlike the laurels, or even the golden medals of academies, and the quiet applause of a few studious men. But the result is not less real, and the advance of knowledge scarcely more indirect. The master-pieces of civil engineering,-the steam engine, the locomotive engine, and the tubular bridge,-are only experiments on the powers of nature on a gigantic scale, and are not to be compassed without inductive skill as remarkable and as truly philosophic as any effort which the man of science exerts, save only the origination of great theories, of which one or two in a hundred years may be considered a liberal allowance. Whilst then we claim for Watt a place amongst the eminent contributors to the progress of science in the eighteenth century, we must reserve a similar one for the Stephensons and Brunels of the present : and, whilst we are proud of the changes wrought by the increase of knowledge during the last twenty-five years on the face of society, we must recollect that these very changes, and the inventions which have occasioned them, have stamped perhaps the most characteristic feature-its intense practicalness-on the science itself of the same period.

It may be doubted whether the above does full justice to the period last mentioned, that in which we are now working. Judging by the history of the past, it is dangerous, perhaps presumptuous, to decide on the real value of labors which we view only in progress, or to estimate the magnitudes of intellectual characters when our very proximity to them confuses the judgment. The Principia was for years a sealed book to most of Newton's contemporaries, and few fellows of the Royal Society recognised in their unpretending secretary, Dr. Thomas Young, the man whom the lapse of a quarter of a century would proclaim the worthy inheritor of Newton's crown. So it may be, that we do not vet seize the full important of such investigations as those of Oersted and Thomson; that we up not foresee the results to which such principles as Joule's Mechanical Equivalence of Heat may lead, or that we fail to observe the significance of those obscure utterances of Faraday in the midst of the brilliant discoveries for which we gladly applaud him. Still more do we think Professor Forbes has underrated our progress in pure mathematics-further on he writes: "No new calculus or great general method in analysis has resulted from these persevering labors, whether of British or foreign mathematicians, but an increased facility and power of applying the existing resources of mathematics to the solution of large classes of problems, previously intractable, or resolved only indirectly or by approximation."

Now we think that the method which is known by the imperfect title of the "separation of symbols," constitutes a really great and distinct step in analysis, not so much on account of what has been achieved by it directly, but in that it has led to a reconsideration of

the base on which our laws of symbolical reasoning are founded, and thence to a total reconstruction of the whole system of abstract analysis. Pushed in various directions, it has resulted in a new geometry, through the quaternions of Sir William Hamilton; in a new and effective method of solving differential equations, in the hands of Professor Boole; and, still more strangely, in an application of analysis, by the same gentleman, to the formal laws of thought ; while several different systems, suited to attacking particular physical problems, have been proposed by various analysts. So many and varied are the ways in which this most fertile principle appears capable of development, that at present the difficulty seems to consist in discovering which will be best to choose. It is perhaps not too much to say, that here the differential calculus has at length generated a successor more powerful than itself, and which will ultimately absorb it. Nor should we forget our acknowledgments to the late Duncan Gregory, who was, if not precisely the inventor, certainly the first to perceive the importance of this method. We venture also to think that Professor Forbes has done scant justice to the progress of analytical geometry; the school, of which Plücker may be considered the founder, constitutes as great an advance upon the geometry of Descartes as his was upon that of the ancients.

That this epoch has not been distinguished "by the full maturity of so many commanding minds" is compensated, and partly accounted for, by the very large increase in the number of cultivators of science. Contrasted with that dreary period in British science which intervened between the death of Newton and the rise of that illustrious band of which Sir J. Herschel may be taken as the type,\* the present day presents itself under a most hopeful aspect; where we can count one British name that emerges above the level for that period, we may count a dozen now, and if their elevation appear less, it may be because the level has risen. In great part this is due to the exertions of those illustrious men above spoken of, whose claim is not only to have done so much themselves, but to have produced a generation worthy to succeed them, and whose glories they justly share; partly also is it due to the improvement in our national seminaries, and the early introduction in them of scientific training, and also partly to the increased demand for scientific qualifications by the advance of engineering and. the kindred arts; but we would fain believe that there is also a real improvement in the average mathematical faculty of the age, and that

<sup>\*</sup> Herschel, Airy, Peacock, Whewell, Babbage, Lubbock.

the powers as well as the thoughts of men are "widened with the process of the suns."

Although this dissertation is headed "A General View of Mathematical and Physical Science," into one important branch thereof, namely, the abstract part, or pure mathematics, Professor Forbes has declined to enter. He says—

The mechanical and experimental sciences alone constitute a body of knowledge so large that it is a responsibility sufficient for one person to attempt to grasp them all, and to set forth in order the steps of progress and improvement which have been so rapid and even so startling. Since some of these have scarcely as yet been historically digested, and the broad features of contemporary discovery have not been gradually separated by the judgment of an impartial posterity from those slighter though praiseworthy details, which lapse of time and advance of knowledge will throw into the shadows of distance,—this most laborious task falls principally upon the reviewer. The length and breadth of the subject of natural philosophy, and the cumbrous and scattered depositories of knowledge in which its records must be sought, combine to render not only the undertaking an arduous one, but the result of it a good deal more bulky than might be desired, or than was easily possible, in dealing with the glorious, but compact, history of Newton's age. It might be compared to the difference between writing a bistory of the Jews or Romans and that of the whole of modern Europe.

The mere magnitude of the undertaking, then, might well excuse me from entering upon the cognate, but exceedingly distinct, subjects of the logic of inductive discovery and the progress of the pure mathematics. But an equally sound reason might be found in my consciousness of inadequacy to undertake, whatever had been the dimensions of my work, a threefold scheme of such magnitude and difficulty. I do not think that any one person could be found to treat the whole as it ought to be treated, and I am certain that I am not that person.

Against such a plea, so urged, nothing can be said, yet it is impossible to help regretting that it should be so. It is true that analysis must always always be subordinate to philosophy, and its very nature is dictated by the requirements of its application to physics ; true also that a physical problem has sometimes suggested the general method in analysis which includes its solution as a particular case, and the practical value of a process is proportional to the number and importance of the problems to which it applies; yet we should remember that every epoch of great physical discovery has been immediately preceded by some grand extension of analysis, and that philosophy has too often long lain helpless till the analyst furnished her with the means of moving. Without the algebra of Descartes and Newton's incthod of series, Newton's Mechanics would have been barren of consequences, and without the integral calculus modern science would be reduced to a skeleton. Just as the immense development of our engineering and commercial enterprise was due to the invention of the slide-rest and the improvements of machinery consequent on this; just

as every enlargement of the domain of experimental discovery may be traced to some refinement of instruments or modes of observing; so has the progress of physical science been related to that of analytical. At the present time the two appear to have, unhappily, somewhat parted company; analysis is going its own way without seeming to heed its companion, and philosophy is dragging heavily from the desertion: or, to quit metaphor, most of our sciences have now reached that point where the problems pressing for solution involve no doubt or difficulty as to the principles to be employed, but are irreducible simply from the enormous difficulty and complication of the analytical processes which at present are at our command. Whether the deadlock is to be got over by the laborious calculations of algorithms—such as tabulating the values of numerous definite integrals—or whether our known methods are to give rise to a new one, which shall at once include and supersede them—who can tell?

Apart from its rendering the history incomplete, Professor Forbes's determination is the more to be regretted from the biographical form which he has adopted, as an apparent injustice arises to individuals whose analytical labors (apart from merit on their own abstract ground) should claim, though indirectly, a share in the triumphs of science. The man who invents a theorem may be, even by its practical outcome, more praiseworthy than he who has made a successful experiment or even determined a natural law.

In filling in the outline which we have already quoted, Professor Forbes has had before him the "History of the Inductive Sciences," and the "Kosmos," works of which praise would be an impertinence; he has, however, wisely evaded coming into competition with these by the plan he has adopted of connecting the history of each science with the biographies of those who contributed to its rise and progress. Whatever is thus lost in the continuity of the history is atoned for by the human interest with which it becomes invested. Some one has remarked that the life of a man of science rarely presents any incidents of interest apart from his science; reciprocally, it is here shewn that the history of science can only be thoroughly understood by aid of the lives of those who have spent themselves in her service. In addition to the physical sciences, Professor Forbes has included the mechanical and kindred arts, and we cannot resist quoting the following eloquent passage, which justifies (if justification were necessary) his course :—

My chief reason for including such subjects as the steam-engine, the strength of materials, and some great examples of construction, and the electric telegraph, is that these important practical improvements are both historically and logically interwoven with the progress of pure and abstract Physics. They have besides impressed upon the character of scientific discoveries of the last hundred years a peculiar stamp which it would have been absurd to ignore while endeavoring, within a moderate compass, and in the plainest language, to convey a vivid though comprehensive sketch of the advancement of natural philosophy during this and the preceding, or, rather, two preceding generations.

It is not to be imagined that the difficulty of the problems which occupy the speculative philosopher, or the comprehensiveness of mind required for their solution, diminishes in any degree as we descend from the regions of pure science to the walks of every-day life-from the vast periods and majestic motions which astronomy enables us to explain and predict, to the common details of the workshop and the railway. In fact, the former are to be regarded as the simpler investigations, whilst our terrestrial agents have their effects modified by the diversified states of aggregation and various mechanical properties of matter, and by the numerous modifications of force arising from heat, electricity, or magnetism, to which it may be exposed. We have as yet made an insignificant advance towards that completer system of natural philosophy of which Newton's will form but one section, in which all the properties of matter and their consequences shall be as well understood as the particular property of gravity is at present. Many of these are to be learned by daily observation of the effects which occur in the ordinary progress of civilisation amongst us. We are continually performing experiments on a great scale and on purely commercial principles, which no individual philosopher or merely scientific society could have ventured to attempt. And in the midst of these appeals to experience, unexpected results are frequently occurring which send us back once more to the study of first principles, which, indeed, while they confound the empiric, do but establish the reputation of the philosophic engineer, who seldom fails to turn them to good account, both in his theory and practice.

We have already expressed our opinion of the manner in which Professor Forbes has performed his task, and so much pleasure have we derived from this performance that we almost feel convicted of ingratitude when the suggestion rises, that our author, in his selection of names for biographical record, has not been quite free from a spice of nativism, or (shall we say?) of that local partiality from which the modern Athens is no more exempt than was the ancient. Certainly, we think the space devoted to one or two individuals might have been curtailed without injury to the work. This, however, is but a small matter, and does not affect its sterling value. To give any abstract or condensation of the subject does not seem feasible within our limits, and we prefer that our readers should take our word that this dissertation is alike essential to the historical student and to him who wishes to take in at one view the many featured image of modern science. If we were to single out particular portions for praise, we should select the biography of Laplace, the history of the discovery of Neptune, the wonderfully curious establishment of the undulatory theory of light by Young and Fresnel, and the glowing descriptions of the dis-

coveries of Davy and Faraday. Perhaps the least satisfactory portion is that on sidereal astronomy. The account of Sir W. Herschel's labors might have been elaborated with more detail, and now that the author of the "Plurality of Worlds" has rendered the "nebular hypothesis" orthodox, we may venture to say that a better account (barring Comte's mistake) than the one Professor Forbes refers to is to be found in that tabooed work, "The Vestiges." We see no reason why the remarkable experiments of Plateau should not have been mentioned in connection with it.

One of the not least advantages of Professor Forbes's arrangement is the interesting contrasts which the personal characters of these heroes-sometimes martyrs-of science present. Consider, for instance, Cavendish, "the descendant of one of England's noblest families, and the possessor of enormous wealth, yet neither of these powerful temptations could withdraw him even for an hour from the course of study which he had marked out, and which constituted for him at once labor and relaxation, the end of living, and almost life itself." He lived for four-score years almost isolated from human intercourse, showing an entire indifference to the ordinary passions and ambitions of mankind; indifferent even to scientific fame, and so strangely incommunicative as to leave much of the nature of his long studies only to be discovered from his manuscript remains. Dr. George Wilson has described him, with characteristic eloquence, as a "wonderful piece of intellectual clock-work. As he lived by rule, so he died by it, predicting his death as if it had been the eclipse of some great luminary, . . . . and counting the very moment when the shadow of the unseen world should enshroud him in its darkness." Contrast with him Davy, the apothecary's apprentice of Penzance, rising in early manhood not only to be the acknowledged leader of chemical science, but also a star of fashion in aristocratic circles; gifted with an ardent and impulsive genius, which enabled him to take theories by storm, and with a fervor of imagination which threw round his great discoveries a poetic glow that dazzled the external world; disdaining to realise money from his inventions, many of which were singly worth a fortune, careless of health and life itself in untried experiments, and in all stages of his short but varied life "acquitting himself gracefully and well." Add to these Wollaston, whose discoveries in chemistry were of hardly less practical value than those of Davy, and who was moreover an original and successful observer in almost every department of philosophy; yet he was quite unknown to the world at large, and appreciated even by few of his contemporary brethren in science. We borrow the following graphic comparison from the dissertation :---

While Davy was delighting crowded audiences with his eloquence, his discoveries, and their wonderful results, Wollaston was pursuing his solitary experiments on a scale so small that scarcely three persons could witness them at once. While Davy was firing his potassium with ice, and making mimic volcanoes heave by the oxidation of his new metals, Wollaston was extracting, by minute analysis, from the refractory and unoxidable ores of platinum, substances previously undetected, which, neither by their quantity nor their characters, could ever interest any but a man of science. While Davy was charging his prodigious battery of 2500 pairs-the largest which has ever been constructed (a homage to his genius, provided by his numerous admirers )- Wollaston was proving, after his fashion, how similar effects could be produced by the very same agency on a small scale; and with no greater apparatus than a sheet of zinc, a few drops of acid, and an old thimble, he would gratify his friends by exhibiting the mimic glow of an almost microscopic wire of platinum.\* Davy seemed born to believe, Wollaston to doubt. Davy was a poet; Wollaston a mathematician, or, at least, capable of becoming a great one. Davy announced his discoveries in fiery haste, and presented all their consequences and corollaries as a free gift to mankind; Wollaston (estimating more truly the rarity of the inventive faculty,) hoarded every observation, turned it over and over, polished it, rendered it exact beyond the reach of criticism, and then deliberately laid it before the world. He had the coldness and the accuracy of Cavendish, but he lacked the spur of his genius, and the wide grasp of his apprehension. Among other legitimate results of discovery, Wollaston was not unwilling to claim for his own the material benefits which such researches sometimes, though rarely, yield; whilst Davy, as we have seen, spurned every possible attribution of an interested motive. Davy never made a shilling in his life, save as an author or a lecturer, (except as paid assistant to Dr. Beddoes); Wollaston realised a fortune by his art of working platinum. Davy was admired by thousands at home and abroad ; Wollaston was little known except to a small circle who could appreciate the resources of a mind rarely opened in confidence to any one, and of which the world was only partially informed. The composure of his death-scene rivalled that of Black and Cavendish. His disorder was one of the brain. When he had lost the power of speech, his attendants remarked aloud that he appeared unconscious. Making a sign for a pencil and paper, he wrote down a column of figures, added them up correctly, and expired.

A still different type is presented by Dalton; born in humble circumstances, a consistent Quaker through life, scantily educated, and laboring under disadvantages of person and manner: he maintained himself in a grade barely above poverty by private teaching, and without friendly encouragement, with deficient means, and apparatus rudely constructed by his own hands, we find him making discoveries by which the world now ranks him as the very first in the annals of Chemistry, yet which were at the time but coldly acknowledged; nor was it till towards the close of a long life that scientific honors were

<sup>\*</sup> So wonderful was his skill in dealing with the minutest quantity of a substance, that it used to be said—give him a scrap of mineral only visible in the microscope, and he will tell you not only what it is, and where it came from, but also the name of the person who quarried it!

awarded to him, and the burden of his daily labor for a livelihood lightened by a small pension from Government. We might go on quoting instance after instance to show how the divine gift of Philosophy is indifferently contained in vessels of every mould and substance. but shall only give one more-the last and perhaps the greatest (one only excepted) the world has yet received-Thomas Young. Like Dalton, born a Quaker, but, unlike him, in easy circumstances and soon throwing off the technical characteristics of his sect : self-educated, he became in early life "an accurate classical scholar; perfectly familiar with the principal European languages; well acquainted with mathematics, and with almost every department of natural philosophy and natural history; profoundly versed in medical and anatomical knowledge, and in possession of more than ordinary personal and ornamental accomplishments."\* It is only within the last few years (though Young died in 1829) that the value of his extensive labors has been fully appreciated ; to enter into them would require a separate article; we can only endorse Professor Forbes's belief that "since Newton (or before him) Thomas Young stands unrivalled in the annals of British (or any other) Science."

It is interesting to notice the very different tracks along which the course of discovery has moved. Sometimes, though not often, the exact Baconian method has been followed, a method which it has long been the fashion to applaud as the only one, but which Bacon's latest editor justly characterises as more adapted to the exclusion of error than the detection of truth ; more frequently, an idea, instinctively seized upon, has been worked out to its full establishment as a natural law; sometimes, a single fortunate experiment has given rise to a whole series of discoveries; while in other cases, some simple law has long been hidden, though involved in numerous experiments, from the eyes of observers, and has only been dragged to light by one coming after them, reaping the fruit which they had sown. It is not uncommon to hear of the large share which accident, so called, has had in the progress of scientific discovery, but an attentive consideration of this progress dispels such a notion. Accidents, it is true, do happen, and are happening every moment : it is only when one happens at the right time and place that results ensue : the seeds of science lie scattered everywhere ; where the soil and circumstances are suited to them, they grow. As the German proverb says-"The world is the same to all, but each eye sees only what it brings with it the power of seeing." We cannot resist quoting Professor Forbes's account (as a model of research) of the invention of the Davy Lamp, often told before but never so well.

<sup>\*</sup> Peacock-Life of Young.

The lamentable loss of life occurring in coal mines from explosions of fire-damp or inflammable air disengaged from the workings, had for many years attracted the attention and sympathy of the public, and had likewise been carefully considered by scientific men. The explosive gas was known to be the light carburetted hydrogen. Two plans alone seemed to present themselves for diminishing the danger :- the one, to remove, or chemically to decompose the fire-damp altogether ; the other, to provide a miners' lamp which, by its construction, should be incapable of causing explosion. The former of these modes of protection, it was soon seen, could only be palliative ; the only efficient form which it took was that of a more effectual ventilation; but the terrific rapidity with which a mine may be suddenly invaded by fire-damp, from channels opened by a single blow of the pickaxe, must prevent it from ever acting as a cure. The latter plan had as yet vielded nothing more effectual than the steel mill long used by miners, which pro \_ duced an uncertain and intermitting light, by the rotation of a steel wheel against a flint, the scintillations of which were incapable of inflaming the fire-damp. The insufficiency of the light prevented it from being used, except in circumstances of known danger. The celebrated Baron Humboldt, Dr. Clanny, and several others had invented safety lamps on different principles, but they were all clumsy and more or less ineffectual.

At last, in the summer of 1815, the Rev. Dr. Grav, (afterwards Bishop of Bristol,) then Chairman of a committee appointed by a benevolent association at Bishop Wearmouth for the prevention of colliery acceidents, applied to Davy, who was then on a sporting tour in Scotland, requesting his advice and assistance. Sir Humphry answered the call with promptitude. On his southward journey, in the latter part of August, he visited the collieries, ascertained the circumstances of the danger which he had to meet, and was provided by Mr. Buddle with specimens of the inflammable air for examination. Within a fortnight after his return to London, he had ascertained new and important qualities of the substance, and had already four schemes on hand for the prevention of accident. Before the end of October, he had arrived at the following principles of operation in connection with a safety-lamp :-- " First. A certain mixture of azote and carbonic acid prevents the explosion of the fire-damp, and this mixture is necessarily formed in the safe-lantern. Secondly. The fire-damp will not explode in tubes or feeders of a certain small diameter. The ingress to, and egress of air from any lantern," he adds, "is through such tubes or feeders; and, therefore, when an explosion is artificially made in the safe-lantern it does not communicate to the external air." The effect of narrow tubes in intercepting the passage of flame is due to the cooling effect of their metallic sides upon the combustible gases of which flame is composed;\* and one of his first and most important observations was the fortunate peculiarity that fire-damp, even when mixed with the amount of air most favorable to combustion (1 part of gas to 7 or 8 of air), requires an unusually high temperature to induce combination. Olefiant gas, carbonic oxide, and sulphuretted hydrogen are all inflamed by iron at a red heat, or ignited charcoal, but carburetted hydrogen does not take fire under a perfect white heat. The earliest safety-lamp consisted of a lantern with horn or glass sides, in which a current of air to supply the flame was admitted below by numerous tubes of small diameter

<sup>\*</sup> This prime fact Davy had obtained from a committee of the R. S. which had been appointed to examine the possibility of gas-explosions being caused by the flame running back through the piping into the gasometer.

or by narrow interstices between concentric tubes of some length; or finally, by rows of parallel partitions of metal, forming rectangular canals extremely narrow in proportion to their length. A similar system of escape apertures was applied at the top of the lantern.

With characteristic ingenuity, Duvy did not stop here. He continued to reduce at once the apertures and length of his metallic guards, until it occurred to him, that wire gauze might, with equal effect, and far more convenience, act upon the temperature of flame, so as to reduce it below the point of ignition, and thus effectually stop its communication. The experiment was successful, and by the 9th November, 1815, or within about ten weeks after his first experiments, an account of the safety-lamp defended by wire gauze was presented to the Royal Society. About two months later he produced a lamp entirely enveloped in metallic tissue.

There are none of Davy's researches which will stand a closer scrutiny than those which terminated thus successfully. No fortuitous observation led him to conceive a happy idea and to apply it to practice. A great boon to humanity and the arts was required at his hands; and, without a moment's delay, he proceeded to seek for it under the guidance of a strictly experimental and inductive philosophy. Without, perhaps, a single false turn, and scarcely a superfluous experiment, he proceeded straight to his goal, guided by the promptings of a happy genius, aided by no common industry. The chemical, the mechanical, and the purely physical parts of the problem were all in turn dealt with, and with equal sagacity. It may be safely affirmed that he who was destitute of any one of these qualifications, must have failed in attaining the object so ardently desired, unless by the aid of some rare good fortune.

In comparing the biographies of foreign celebrities with those of British origin, we cannot help being struck with a difference that manifests itself in the treatment they receive from their respective countries. Abroad, we find that the successful cultivators of science are raised to places of dignity and trust in the State, adorned with distinctions of crosses and ribands, and liberally provided for, when necessary, by honorable pensions; not a few of them accomodated with titles of nobility in acknowledgment of their services. At home, on the contrary, with the exception of a few knighthoods (rather indiscriminately conferred), and now and then a solitary baronetey, or perhaps a small pension grudgingly bestowed, we find no official recognition of the status of a man of science. This has sometimes, by foreigners, been made the ground of illiberal comparison, yet surely without due consideration. The indiscriminate bestowal of such honors as are extended to men of science in England, sufficiently proves how incapable are the political advisers of the Crown to form a court of honor for her intellectual peerage. A Royal Society presidency, or a Wollaston medal, constitute far fitter honors for a Newton or a Lyell than the legislative honors and functions which supply the highest reward for the successful soldier or lawyer ; while the loss is that of the

exclusive order of hereditary legislators and not of the men of science. The order of England's peerage would certainly have sustained no degradation, had it been able to reckon among its noble descents, those who counted kin with the Lincolnshire farmer's boy, or with the son of the German drummer who added so largely to the domain of knowledge by his brilliant genius and varied talents; but it may be doubted if either Newton or the Herschels would have been the gainers by their transference from the ranks of England's untitled nobles, to those of her hereditary peerage. Foreign sneerers and domestic grumblers may consider these things and learn wisdom, or, at the least, gather the comforting conviction, that if British science has gone on so well and long without the bedizenment of aristocratic trappings, these latter may not be essential to her still further progress. We earnestly hope that Professor Forbes may live to record, for the next quarter-century, even greater achievements than those which he has here so admirably set forth.

## SCIENTIFIC AND LITERARY NOTES.

## PHYSIOLOGY AND NATURAL HISTORY.

#### ABNORMAL INDIAN CORN.

Dr. H. Boys, of Barrie, in a letter to Professor Croft, of date 29th July, thus writes; "In the last number of the Canadian Journal, at p. 309, Professor Wilson is stated to have read before the Institute some remarks on a specimen of Indian corn, having male and female flowers developed on the same stalk. In reference to this I send you a rough sketch I made some years back of a similar anomaly, which fell under my own observation. You will perceive this case offered more deviations from nature than are mentioned in the Journal as being noted by Professor Wilson. I consider the subject one involving points of the greatest interest to animal and vegetable physiologists. In thus noting the deviations occurring in the simple structure of vegetables, an opportunity may be afforded of investigating such phenomena, with a fair chance of leading to important results. I hope the subject will not be allowed to drop. All I can promise to do is to look out for fresh instances, and should I be so fortunate as to observe such this season, I shall endeavour to make more careful drawings and more minute and accurate remarks, and shall send you the result."

In the sketch which accompanies the letter of Dr. Boys, the branched spike of male florets is seen with a considerable group of the female introduced among

them, and in this group still further anomalies are noticeable. While the greater number of the florets are females, some of them are hermaphrodite, and others in the same flower have a male and female floret, each with its distinct calyx within the same glumes. The ovum is therefore, in this plant, exhibited in every form of development, and its sex is so capriciously distributed as to favor the idea of some phytologists that the sex is not determined at the origin of the ovum, but by subsequent casual circumstances.

#### COLEOPTERA.

In the last number of the Proceedings of the Academy of Natural Sciences, of Philadelphia, Dr. Leconte has added to his invaluable series of monographs of North American Coleoptera one on the Pselaphidæ. The paper contains an enumeration of the species and descriptions of those which are new. Of Dyschirius, twenty-eight; Acephorus, one; Ardistomis, four; Aspidoglossa, one; Clivina, twenty-seven; Schizogenius, six.

#### NEUROPTERA.

Uhler has described seven new species of Libellula, inhabiting the United States.

#### MOLLUSCA.

Lea describes a number of new species of Naiades, principally Uniones, from Alabama, North Carolina, and other parts of the States. Under the rather curious heading of "Gnotic Species," he describes the following:

Unio Canadiensis. Testâ lævi, triangulari, subcompressa inæquilaterali, posticè obtusè angulatâ, valvulis subcrassis, anticè crassioribus; natibus subprominentibus; epiderme luteâ, postice radiatâ; dentibus cardinalibus parvis, erectis crenulatisque; lateralibus longis, curvis lamellatisque; margaritâ albâ et iridiscente. Hab. St. Lawrence River, near Montreal.

#### THE CANADIAN HUMMING BIRD.

During the present summer we were visited by Mr. John Gould, the distinguished Naturalist, whose chief object in his tour through Canada was for the purpose of studying the habits and manners of the species of Trochilus frequenting this portion of the North American Continent. Shortly after his return to England, at a meeting of the London Zoological Society, Mr. Gould detailed some of the results of his observations. He arrived in Canada just before the period of the migration of these beautiful little birds from Mexico to the north, and had ample opportunities for observing them in a state of nature. Their actions he described as very peculiar and quife different from those of all other birds; the flight is performed by a motion of the wings so rapid as to be almost imperceptible; indeed, the muscular power of this little creature appears to be very great in every respect, as independently of its rapid and sustained flight, it grasps the small twigs, flowers, &c., upon which it alights with the utmost tenacity. It are pears to be most active in the morning and evening, and to pass the middle of the day in a state of sleepy torpor. Occasionally of the stability butch numbers that fifty or sixty may be seen in a single tree. When captured, they stoedily becomes tame that it will feed from the hand or mouth within half an hour. Mr. Gould having been successful in keeping one alive in a gauze bag attached to his breast button for three days, during which it readily fed from a small bottle filled with a syrup of brown sugar and water, he determined to make an attempt to bring some

living examples to England, in which he succeeded, but unfortunately they did not long survive their arrival; had they lived, it was his intention to have sent them to the Zoological Society's gardens, where they would doubtless have been objects of great attraction.

Mr. Gould exhibited a highly interesting species of *Ceriornis*, which he had found in the collection of Dr. Cabot, of Boston, who, with great liberality, permitted him to take it to England for the purpose of comparison and description. For this new bird, forming the fourth species of the genus, Mr. Gould proposes the name of *Ceriornis Caboti*.

## CANADIAN INSTITUTE.

FIFTEENTH ORDINARY MEETING .- 4th April, 1857.

Professor E. J. CHAPMAN, Vice-President, in the Chair.

The following Gentlemen were elected Members:

WILLIAM ANDERSON, Esq., Toronto. W. H. BOULTON, Esq., Toronto.

The following Reports of Committees were then read :

1. The BARON DE ROTTENBURG submitted to the meeting, the Report of the Committee on Mr. Ketchum's offer of two acres of land on Yonge Street, for an Astronomical Observatory, recommending the acceptance of the gift, and an application to the Government for aid to accomplish the object in view.

On motion of Professor Croft, seconded by J. G. Hodgins, Esq., the Report was approved of, and it was resolved, that Mr. Ketchum's offer be accepted, and that a copy of the report be transmitted to him, with a special vote of thanks of the Institute for his generous donation.

2. Professor WILSON submitted to the meeting, the Report of the Building Committee, detailing the steps which have been taken by the Committee towards the erection of the proposed new building for the Institute, on the site presented by G. W. Allan, Esq., for that purpose, on Pembroke Street.

On motion of A. H. Armour, Esq., seconded by Dr. George Beattie: It was resolved, that the Report be adopted.

The following papers were then read:

1. By the BARON DE ROTTENBUEG :

"On the Planetary appearance of stars of the 1st and 2nd magnitudes, on the night of the 12th March, and the occultation of Spica Virginis by the moon, on the morning of the 13th March, 1857."

2. By Professor CHAPMAN :

A communication from Dr. G. D. Gibb, of London, England: "On calcareous concretions from Buckinghamshire, England, which have excited considerable attention recently, from certain examples figured and described in the *Illustrated London News*, as vegetable fossils."

#### CANADIAN INSTITUTE.

Professor Chapman exhibited, and commented on a collection of these English concretionary bodies, presented to the Institute, through Dr. Gibb, by Mr. Stowe of Buckingham: and also exhibited and presented to the Institute, specimens of some peculiar silicious concretions,—hitherto, he believed unnoticed,—from the Black River Linestone, of the Lake of St. John, near the Indian village of Rama, lying to the north-east of Lake Simcoe, Canada West.

SIXTEENTH ORDINARY MEETING .- 18th April, 1857.

Col. BARON DE ROTTENBURG, Vice-President, in the Chair.

The following Donations for the Library were announced, and the thanks of the Institute voted to the Donors:

1. From the Geological Society of Dublin :

"Vols. 1, (wanting part 1,) 2, 3, 4, 5, 6, and part 1 of vol 7, of the Journal of the Geological Society of Dublin."

2. From the Author:

"Observations on the construction of an Hospital for the Insane. (Pamphlet.) By B. R. MORRIS, B.A., M.D., :

"Theory as to the cause of Insanity, (Pamphlet.) By B. R. Morris, B.A., M.D.'

The following Gentlemen were elected Members :

OLIVER WELLS, Esq., Crown Land Department, Three Rivers, C. E.

CHARLES B. CHALMERS, ESq., F.R.A S., Barrie, C.W.

The following papers were then read:

1. By Prof. CHERRIMAN, M.A., : "On Vision."

2. By J. HIRCHFELDER, Esq., :

"Observations on bedding out plants."

3. By Professor CHAPMAN:

"On the occurrence of the Genus Cryptoceras in Silurian Rocks."

This being the last meeting of the Session, T. W. Birchall, Esq, and Samuel Spreull, Esq., were appointed Auditors, in accordance with the laws. The Chairman, after congratulating the members on the prosperous state of the Institute, and the valuable communications from time to time submitted to the meetings, by which their attraction have been maintained with undiminished interest, invited the attention of the members to such subjects of scientific value as might come under their notice during the summer recess, with a view to communications to be brought under the notice of the Institute, either through the medium of the Journal, or at the meetings of next session, and adjourned the meeting till November.

MONTHLY METEOROLOGICAL REGISTER, AT THE PROVINCIAL MAGNETICAL OBSERVATORY, TORONTO, CANADA WEST-JUNE, 1857.

## NEW SERIES.

## No. XII.—NOVEMBER, 1857.

# ON THE EARLY DISCOVERIES OF THE FRENCH IN NORTH AMERICA.

BY JOHN LANGTON, M. A., VICE CHANCELLOR OF THE UNIVERSITY OF TORONTO.

Read before the Canadian Institute, February 14th, 1857.

I do not design in the present paper to enter into any detail respecting the whole of the discoveries of the French in North America, but in presenting to the Institute a collection of tracings from old French maps, more peculiarly relating to Western Canada, I propose to offer some remarks in illustration of them.

A very exaggerated impression has gone abroad as to the extent and accuracy of the knowledge possessed by the French of the country which they occupied, and I have more than once seen it asserted in the public prints, that they knew more of the interior than we do even now, excepting in those parts which have been actually surveyed and laid out for settlement. It is not always easy to trace the origin of such popularly received opinions, which are repeated till they become accepted, without inquiry, as acknowledged facts; but, in the present instance, the impression seems to have arisen from a series of maps, possessed by the Library of Parliament, which have been copied from those which are preserved in the various archives in France. To speak of these maps, however, as surveys, as I have heard them described, is to do them by no means justice. They make no pretensions to any such accuracy. The great majority of them, except some plans of towns and particular localities in Lower Canada, are rough delineations of the country, either from the personal observation of the explorers,

VOL. II.-B\*

or from the description of others, giving the estimated distances and directions of rivers, lakes, and portages, which the travellers followed, with here and there an observation for latitude, which, when they are given. I have often found to be a degree or more in error. Still, most of them are interesting, as amongst the earliest records of our country, and there is no doubt that, in some sections of the Province particularly, some of them do give details, which appear no where in our published maps, and are not to be found in the records of the Crown Lands Office. This arises in a great measure from that tendency to centralization, which has always characterized the French nation. If any trader or missionary had penetrated into an unknown region, a description of it was sure, sooner or later, to find its way to the Intendant, and by him was transmitted to the Government at home; whilst with us, if an individual hunter or lumberer has obtained a detailed knowledge of a particular locality, he does not feel in any way bound to report it to Mr. Cauchon, and he would still less think of transmitting it to Downing-street. I have seen private charts in considerable detail, of the country between the Ottawa and Lake Huron, where our published maps present nothing but a blank ; and I myself, nearly twenty years ago, made a map, from my own knowledge and the descriptions of hunters and others, of several chains of lakes, forming the head waters of the River Trent, which are still only partially laid down with any correctness, partly by Mr. Murray, of the Geological Survey, and partly from some exploratory lines run last year by order of the Crown Lands Department. All such rough plans have the same distinguishing feature, that the distances are very much exaggerated, especially the portages; for, when you have a heavy pack or a canoe on your shoulders, a mile assumes very formidable proportions. The same thing is observable in these French maps. The latest discovery generally is unnaturally enlarged, and though the easy observation for latitude keeps the distances from north to south within reasonable hounds, those from east to west, where there is no such check, attain very exaggerated proportions.

But it is not for the geographical information to be obtained from them, so much as for their historical interest, that I propose introducing these maps to the Institute. It must, however, be confessed that there is a great drawback to their value in this point of view, in the fact that some of them bear no date, nor is there any record accompanying them of the source from which they were obtained; but many of them possess internal evidence of their origin, and of the period to which they relate; and I have selected for copying, those which are of the most general interest, especially for us Upper Canadians, which I

will illustrate by a short sketch of the progress of French discoveries on this continent.

Although Jacques Cartier entered the St. Lawrence in the first half of the sixteenth century, it was not till the beginning of the seventeenth that any sustained effort was made towards a permanent occupation of the country. A few trading visits were made from time to time; but at the period of Champlain's first voyage, in 1603, it is doubtful whether there was any establishment even at Tadousac, where parties regularly wintered, and certainly there was nothing beyond. He proceeded up the river as far as the Sault St. Louis, now the La Chine Rapids, and having crossed the portage to obtain a view of the country beyond, he returned to France, and devoted the following years to exploring the Atlantic coast of Maine, Nova Scotia, New Brunswick and Gaspé. It was not till the year 1608 that he returned to the St. Lawrence, and built the first house at Quebec.

Champlain at once entered into friendly relations with the Indians inhabiting the northern shore of the St. Lawrence. The Montagnets, from Quebec downwards, and higher up the Algoumequins, as he designates them, who were afterwards called Algonquins, together with allied tribes of various names, from the Ottawa country, appear all to have belonged to the great Chippewa family, which still extends over nearly a quarter of the continent. He also fell in with parties of the Ochateguins, or Hurons, as they are subsequently called, their own name for themselves being Yendats, or Wyandots, according to the English pronunciation. It was this tribe apparently that Cartier had found in occupation of the island of Montreal, but their settlements were now exclusively on the great lake which the French called by their name, and they only came down to the St. Lawrence for the purposes of trade. They belonged to the same race as the Iroquois, though at that time at deadly enmity with them. With the Iroquois themselves, called by the English the Five Nations, who occupied the south bank of Lake Ontario and the upper St. Lawrence, no cordiality ever existed, to the end of the French rule in Canada.

The very next spring after his arrival, with two or three companions, Champlain joined the Algonquins and Hurons in an expedition against the Iroquois, and having proceeded up the river Richelieu to the lake which still bears his name, he defeated them near where Ticonderoga now stands. During these earlier years Champlain himself seems generally to have returned to France for the winter, but some of his party remained behind at Quebec, or at another station on the island of St. Croix, and one of them accompanied a party of Algonquins to the upper Ottawa, in exchange for an Indian, whom Champlain took with him to France. Hearing from this man, on his return in the spring of 1612, that by the route of the Ottawa he could reach the North Sea, where the English had in the meantime discovered Hudson's Bay, he proceeded up the Ottawa, giving a very clear description of the rapids and portages, and the confluence of the Rideau, Madawaska, and other streams, and reached as far as the great Alumette Island, which was the seat of the principal Algonquin Chief in those parts. Finding, however, that he had been deceived as to the probability of reaching the North Sea, and the Indians being unwilling to accompany him farther, he once more returned to France, and spent three years there in trying to induce some of the leading nobility to take his infant colony under their patronage.

This is the period of the first maps which I have seen. They bear date 1603, 1607, and 1609; but the most extensive is that published in 1613, with the first account of Champlain's voyages. It is not amongst those which I have copied. It gives his discoveries on the Atlantic coast, on the lower St. Lawrence, and the Ottawa, and indicates the existence of a large lake, from which the St. Lawrence flows.

Immediately upon his return in 1615, he joined, with about a dozen companions in another expedition against the Iroquois, the details of which are more particularly interesting to us, not only because it gave rise to the most important of the early discoveries, but because it was the first introduction of civilized man into what is now Upper Canada. Seeing that the Iroquois were seated on the south bank of the St. Lawrence, and their chief villages were amongst those lakes and rivers south of Lake Ontario which still bear the English names for the different tribes, he took a very curious road to reach them. It must, however, be remembered, that his Indian allies had to return home to collect their forces. He ascended the Ottawa beyond the limit of his first journey, till he branched off into the chain of small lakes, which led him to the Lake of the Epicerini, or Nebicerini, as later writers call them, an Algonquin tribe, who were long celebrated for their power as sorcerers, and whose name we still preserve in that of Lake Nipissing. Descending the river which flows out of that lake, he reached the great lake of the Attagouantans, or the fresh water sea of the Hurons, which he tells us is three hundred leagues from east to west, and fifty leagues wide. Turning to the east, and coasting along the northern shore, he crossed a bay at the end of the lake (Matchedash Bay) to a fine country which was the home of the Hurons. Proceeding from village to village, the names of several of which he gives, all of them evidently situated on Matchedash Bay, and between that and Lake Simcoe, he arrived at the chief place of the tribe, which he calls Cahiagué, situated apparently
somewhere in Oro or Orillia. After remaining there for a while to collect their forces, the party carry over land for three leagues to a small lake, which is connected by a narrow place with a large one twenty-six leagues round, and crossing the large lake, which, of course, is Lake Simcoe, they make a portage of ten leagues (really about half that distance) to another lake, below which is a fall, and from whence flows a river, which, after a course of sixty-four leagues, falls into the great lake of the Entouhonerons. Champlain describes this river, the course of which they followed, as running through beautiful lakes and a fine country, formerly thickly inhabited and cultivated, but at the time of his visit entirely deserted on account of the wars. This mention of extensive cultivation amongst the Indians is somewhat foreign to our notions, but it must be remembered, that though the Algonquin tribes were a wandering race of hunters, the Hurons and Five Nation Indians are always described as cultivating the soil, and living in permanent villages; and it is one of the hardships complained of by the missionaries, that they could rarely get any meat, but lived principally upon sagamité, with occasionally some fish. Champlain says that on their route they had five portages, some of which were four or five leagues long, whereas the only long carrying place between Balsam Lake and the Bay of Quinte is that from Mud Lake to Peterborough, about seven miles. This makes me suspect that they did not follow the course of the main river, but, being desirous of concealment, kept in the back country, and carrying over into the lakes of Belmont and Marmora, re-entered the Trent by Crow River. However this may be, they reach the Lake of the Entouhonerons, cross its eastern extremity, out of which the St. Lawrence flows, and after coasting along for some distance, leave their canoes, and make a four-days journey through the woods, crossing on their way a river, which comes from a large lake, (evidently Oneida Lake,) and so reach the village of the Iroquois, which was their destination. Being repulsed, however, and Champlain himself wounded, they retreat to their canoes, re-cross the lake, and ascend a river for twelve leagues, which, after a portage, brings them to a large lake ten or twelve leagues in extent. The description accords very well with Rice Lake, but it conveys the impression that it was not the same route by which they descended, which strengthens my conjecture as to their former course, for I know of no other large lake they could have reached in this manner, Longborough Lake lying too far out of their course. Here they remained hunting till the frost enabled them to return home over the ice. During the winter Champlain visited some tribes farther south, one of which, the Tobacco-growers, seem to have been located about Guelph; and he had intended pushing on in the

spring to a great lake he heard of above, beyond which, he was told, the buffaloes were to be found, whose skins he saw among the Hurons; but dissensions breaking out amongst his Indian allies, he returned to Quebec by the way he came, and for the rest of his life devoted himself to the care of the colony on the lower St. Lawrence.

The oldest map in this collection will illustrate the geographical knowledge obtained by Champlain's great expedition. It bears date, indeed, twenty years later, but it contains hardly anything but what is to be found in Champlain's account. It is almost identical with the map accompanying his second publication, and is, indeed, evidently copied from it, even to the rectangular islands on Hudson's Bay, and some marks, which mean nothing as they stand here, but in the published map refer to descriptions in the body of the work. Some additions were doubtless made to their knowledge in the interval between the great expedition and the date of the publication of Champlain's journal in 1632, for the Jesuits and Recollets had established missions amongst the Huron villages; but if we may judge from Sagard's journal, in 1622 and '23, the accessions would not be very great, for, interesting as it is in other respects, the geographical details are so meagre that you can only make out that he went and returned by Lake Nipissing. As to the additions between Champlain's publication and the date of the map, they only amount to six names, which I have underscored in red ink, and I have added, instead of the bare names in other parts, numbers in red ink referring to Champlain's descriptions, of which I append a copy. So unlike the reality is this map, that at first sight one would hardly make out what it is intended to represent. Lake Huron assumes a shape as dissimilar from the truth as can well be conceived. An imaginary lake appears to the north of Lake Huron, near Sault Ste. Marie, which, as it bears the same name, probably records a misunderstood description of Lake Michigan ; and Lake Erie disappears altogether, being replaced by a simple river. The latter lake was however known, as one of the missionaries to the Hurons had penetrated as far the year before the date of the map, a trace of which is found in the addition of the name Lac des Eriés; but the configuration given by Champlain remains unaltered, and there is nothing but a river, on which it is said there is a great fall, at which quantities of fish are carried over and stunned.

The small accession of knowledge between 1614 and 1643 is of itself negative evidence of what we know from other sources, the pause in the course of discovery which took place after Champlain's expedition. Times, indeed, were approaching which were not favor-

398

able to discovery. In 1629 the English took Quebec, and held the colony for some years-no great feat of valour certainly, as there were no settlements except at Quebec and Tadousac, and a missionary station at Three Rivers ; and in 1622, according to Charlevoix, there were only fifty souls at Quebec, including women and children. Almost immediately after Canada had been restored to France, the Iroquois wars commenced, which for many years confined the French to the lower St. Lawrence, and ended in the almost entire extermination of their Indian allies. The missionaries, it is true, adhered nobly to their converts, and in many instances perished with them; and when the remnants retired into the Far West and the Far North, they accompanied them, and so gained some acquaintance with more remote regions; but no discovery of importance is recorded. It was not till a temporary peace was made in 1669 that the adventurous spirit of the French settlers had room to display itself, and that they penetrated into the country occupied by the Iroquois.

The second map, in point of time, belongs to this period. It bears date 1670, and records the journey of two missionaries, Dolier and Galliné, who appear to have been the first, or amongst the first, who reached Lake Huron by the route of Lakes Ontario and Erie. I have found no other account of their travels, nor are their names mentioned by Charlevoix, any more than that of M. Perray, who appears to have made a portage from somewhere near Toronto to Lake Simcoe, unless he be the M. Perrot who, about the same time, was employed in negotiating with the western tribes. A letter of the Intendant, Talon, is referred to, which may probably be amongst our MS collection-detained at Quebec upon the somewhat far-fetched excuse, that it may be wanted to elucidate some knotty point connected with the Seignorial Tenure. The missionaries appear to have been very conscientious observers, distinguishing between what they have seen themselves and what they know only by report, and for gentlemen of their sacred calling, they take an unusual interest in all that pertains to the chase. There are two noticeable features about this map. The indefinite extension of Lake Erie westward, to be found in all the maps of this period, where Hennepin, nearly twenty years later, says no one had yet penetrated, for which this sufficient reason may be given, that no such extension exists in nature; and the singular delineation of Lake Huron, where the eastern shores are not very incorrectly given, nor the western shores of Lake Michigan, but there is an entire ignoring of the great peninsula of Michigan. This is the more surprising, as they appear to have penetrated beyond the Straits of Mackinaw, and one can hardly account for their knowing nothing of the opposite shore.

From this period the progress of discovery was rapid. Perrot was very succesful in his negotiations with the tribes round Lake Michigan, who, at a great gathering at Mackinaw, acknowledged the supremacy of France; and the new Governor, Count Frontenac, built the fort which long bore his name, where Kingston now stands. This was the first step which curbed the power of the Iroquois, and afforded any security to the French trade on Ontario. Other forts were soon after built at Niagara, Detroit, and on Lake Huron, which rendered French influence predominant over all the great Lakes. Important discoveries followed each other rapidly. Joliet and Marquette ascended the Outagami from Green Bay on Lake Michigan, and carrying across to the Wisconsin River, followed it down to the Mississippi, which they descended as far as the confluence of the Arkansas, when being satisfied that it flowed into the Gulf of Mexico, they returned by the way of Illinois River to the extremity of Lake Michigan. The latter route was soon after pursued by La Salle with larger means, the Mississippi was followed to its mouth, and a colony founded there.

I have copied Joliet's own map, and his letter to Frontenac giving a brief description of the newly discovered countries.\* Father Marquette published a short account of their journey, with a very indifferent map, but this is the only record from Joliet himself, and he gives a pathetic relation of its conclusion; how after escaping all the dangers of a difficult and unknown navigation, amidst hostile Indians, his canoe was upset in sight of the house from which he started, two of his party, his journal and all his baggage were lost, and he brought home nothing but his life.<sup>+</sup> The inscription in red ink is apparently of a later date,

400

<sup>\*</sup>Accurate tracings of this and the other maps referred to, in illustration of the paper, have been deposited by the author in the Library of the Canadian Institute.

 $<sup>\</sup>dagger$  The following letter of Joliet to Frontenac, copied from the above map, is interesting as the sole memorial he has left of his expedition :—

Monseigneur le Comte de Frontenac, Conseiller du Roy en ses Conseils, Gouverneur et Lieutenant-general pour sa Majesté en Canada, Acadie, Isle de Terreneuve et autres pays de la France septentrionale.

Monseigneur,—C'est avec bien de la joye que j'ay le bonheur aujourd-hui de vous presente cette carte, qui vous ferra connoître la situation des rivières et des lacs sur lesquels ou navigue au travers du Canada ou Amerique septentionale, qui a plus de l200 lieus de l'est à l'ouest. Cette grande rivière, qui porte le nom the Rivière Colbert, pour avoir esté decouverte ces derniers années 1673 and 1674, par les premiers ordres que vous me donnates entrant dans votre gouvernement de la Nouvelle France, passe au-dela des Lacs Hurons et Illinois, entre la Floride et le Mexique, et pour se decharger dans la mer coupe le plus beau pays qui se puisse voir sur la Terre. Je n'ay rien vou de plus beau dans la France que la quantité de prairies que j'y ay admirés tous les jours, ny rien d'agréable comme la diversité des bocage et des forets, ou se ccuillent des prunes, des pommes, des grenades, des citrons, des meures,

although the account of the river by which you may go to California, may have been subsequently added by Joliet himself. But the lower inscription is clearly an error, for La Salle did not reach the Mississippi by the Ohio, as there stated, but by the Illinois.

La Salle's expedition is better known perhaps than any of the former ones, from Father Hennepin's journal. I find amongst the collection of maps many relating to the Mississippi, and also several to the North-western waters running into Lake Winnepeg; but I have confined myself more especially to Canada and shall not pursue the subject any further. I have added, however, two maps relating to this period. One, bearing the date 1688, is very rude, but it is interesting as shewing the principal settlements of the Iroquois south of Lake Ontario, which appears to have been the main object in view. The other has no date, but was evidently made a little earlier. It is clearly after 1678, as Fort Frontenac is set down, and it gives the portages by which Joliet reached, and returned from, the great River Colbert, as he calls it; but it cannot be of much later date, as it gives the Indian name of the Salmon River, at the south-east extremity of Lake Ontario, which after the sufferings of De LaBarre's expedition in 1683 was always called la Famine, and it makes no mention of Fort Niagara, which was built in 1685. It is a well executed map upon the whole, and interesting from the full detail which it gives of the habitats of the various Indian tribes. It is melancholy to look over it, and compare it with the earliest map in this collection, which is anterior to it by only about 40 years. The Iroquois wars had told their tale in the

Monseigneur,

Vostre très humble et très obeissant serviteur,

JOLIET.

et plusieurs petits fruits qui ne sont point en Europe. Dans les champs on fait lever des cailles, dans les bois on voit voler les perroquets, dans les rivières on prend des poissons qui nous sont incounus pour leur goust, figure et grosseur.

Les mines de fer; les pierres sanguines qui ne s'amassent jamais que parmy le cuivre rouge n'y sont pas rares; non plus que l'ardoise, le salpetre, les marbres, et moulanges et charbon de terre : pour le cuivre le plus grand morceau que j'ay veu estoit comme le poing, et tres purifié, il fut decouvert auprès des pierres sauguines qui sont beaucoup meilleurs que celles de France et en quantité. Tous les sauvages ont des canots de bois de 50 pieds le long; pour nourriture ils ne font pas d'etal de cerfs, ils tuent des bufies qui marchent par bandes de 30 et 50, meme j'en ay compté jusques à 400 sur le bord de la rivière, et les coqs d'inde y sont si communs qu'or n'en fait pas grand cas. Ils font des bleds d'inde la plus part trois fois l'année, et tous des melons d'eau pour se rafraichir pendant les chaleurs, qui n'y permettent point de glaces et fort peu de neiges. Ou auroit veu la description de tout dans mon journal si le bonheur qui m'avait toujours accompagné dans ce voyage ne m'eut manqué un quart d'heure devant que d'arriver au lieu d'ou j'estois party. J'avois évité tous les dangers des sauvages, j'avois passé 42 rapides et j'estois prest de debarquer avec toute la joye qu'on pouvoit avoir du succés d'une si longue et si difficile entreprise lorsque mon canot tourna hors des dangers, j'y perdis 2 hommes et ma cassette à la veue des premieres habitations françois que j'avois quittées il y avoit presque 2 ans, il ne me reste que la vie et la volonté pour l'employer à tout ce qui il vous plaira avec toute la joye possible.

mean time, and where Champlain indicates populous tribes we find here only Hurons, Eries, &c., "nation detruite."

The last map relating to Upper Canada is not copied from any old map, but represents Lake Ontario as it is, with the various names which are given in different maps and descriptions to localities on its shores, and I have added to it a somewhat enlarged copy of Creuxius' topography of the Huron villages near Lake Simcoe.\* There is considerable confusion in these different names. One name which is variously written as Tejajagon, Teyogagon, Terraiagon, &c., is generally placed in the neighbourhood of Toronto, but Hennepin gives a similar name to a place 17 leagues above Kingston, and one of the maps to a place on Burlington Bay. Another place called Ganaraské is apparently Port Hope, but Lahontan gives that name to Burlington Bay also. As for the names given in Creuxius's map, bearing date 1660, either to places on our shore of Lake Ontario, or to the Huron villages round Lake Simcoe, I have hardly been able to identify one of them with any name which appears elsewhere. The carrying place to Lake Simcoe does not appear to have been at Toronto, but at some place considerably to the east of it, at the Rouge perhaps, and its name with various modifications of spelling, may be called Ganatchikiagon. As for the name Toronto, in the earlier maps it is always given to Lake Simcoe, and in the Huron language seems to have meant much or multitude, but Creuxius calls Lake Simcoe Lacus Ouentaronius. I do not find Toronto applied to its present locality till a map, which illustrates the campaign which ended in Braddocks defeat in 1755, when there appears to have been a French Fort here.

The remaining map belongs to Lower Canada exclusively, and to a portion of it which, being under lease to the Hudson's Bay Company at the munificent rent of £50 a year, is hardly at all known at present. It bears date 1735, and professes to be the first map that ever was made of that region, which was the Crown domain. It is compiled by a Jesuit living at Chicoutimi, and if it is not more accurate at a distance than it is within 30 or 40 miles from his own door, the great detail into which it enters cannot be much relied upon. It is, however, a curious map, with a very flowery dedication to the Dauphin,

402

<sup>\*</sup>The accompanying map, engraved for the Journal from the original in Father Ducreux's *Historia Canadensis*, Paris 1664, represents the region around Lake Simcoe as laid down in 1660. Unfortunately the *narrows* which form the junction between Lake Simcoe and the little Lake Couchiching have been omitted, probably through the carelessness of the engraver, but in other respects the outlines are surprizingly accurate. The Indian names, however appear to be hopelessly corrupt and their Latin dress adds to the difficulty of identifying them. Lacus Ouentaronius may perhaps be read Ouen-tarontus in accordance with the name elsewhere assigned to Lake Simcoe.

and a Latin inscription, which I submit as a puzzle to any members of the Institute, who are curious in such things.\*

There are not so many details of the discoveries in this direction. and they are not of as interesting a character. Although Tadousac was so long the most important station in Canada, it was not till 1647 that the French reached Lake St. John. In 1663 they had penetrated as far as Hudson's Bay. Tadousac was the principal site of the Indian trade, long after Quebec had become the capital of the colony, and some of the oldest missionary settlements are on the Saguenay. In Champlain's time, the island of Montreal seems almost to have vied with it as a trading place for the Indians, who followed the route of the Ottawa, and Champlain himself built a house near where the Victoria Bridge crosses, though the trading rendezvous seems to have been at the back of the island, on the Riviere des Prairies. But the Iroquois wars must have rendered such a station too insecure, as no town or fort was built there till 1641, and the Indians even from Lake Huron used to ascend the streams, which fall into the Ottawa from the North, and after a portage, used to descend the St. Maurice to Three Rivers, or the Saguenay to Tadousac. Even as late as 1670, Charlevoix tells us that there were rarely less than 1200 Indians to be seen encamped at Tadousac during the trading season ; but the ravages of the small-pox amongst the Northern tribes about that period, put an end to the trade of Tadousac and Three Rivers. Some nations were no more heard of. They were exterminated, amalgamated with other tribes, or carried their furs to the English fort on Hudson's Bay. Montreal, which was now rising into importance, became the chief seat of the trade, and Tadousac was deserted.

In tracing the history of these discoveries, one cannot but be struck with the extraordinary rapidity with which the French spread themselves over the continent, as compared with the progress of the English. The commencement of the colony may date from the foundation of Quebec by Champlain in 1608, one year after the permanent establishment of the English at Jamestown, and one year before the discovery of the Hudson River, and twelve years before the landing of the Pilgrim Fathers at Plymouth. The colonies therefore commenced nearly on equal terms, yet within 8 years the French had reached Lake Huron, whilst it was nearly a century before the English had extended to any considerable distance from the sea coast. The Iroquois wars now broke out, which for many years confined the French almost entirely to the Lower St. Lawrence, but no sooner were they brought to

<sup>\*</sup> His in quam supersedimus in hoc 4ta editione ne doctiores veniant Romani et tollant nostram gentem propinante ad nauseam Baccho.

a close, or rather succeeded by a hollow truce, than the tide of discovery, which had been pent up, spread over the whole continent, and in a very few years extended to the North Sea, the Gulf of Mexico, and almost to the Rocky Mountains. Much of this difference must no doubt be ascribed to the facilities afforded by our immense chain of Lakes and Rivers, and to the character of the Indians with whom the French were brought into contact, for they never made any progress in the direction of the warlike Iroquois. Something may also be due to the missionary spirit of the Jesuits and Recollets, who penetrated in spite of dangers and privations to every tribe where there was a chance of propagating the faith, and something to the ambition of their home government, which prompted to the acquisition of new territory, whilst the British colonies were left very much to themselves. But much is still to be attributed to the national character of the settlers. The Englishman, grave and earnest, settled himself at once on his farm, and devoted any leisure he could spare to framing laws for the government of the society which surrounded him, and to enforcing them with the stringency of a man, who having strong convictions himself, is very intolerant of any body who deviates from his notion of right. He was essentially a member of a community, and rarely pushed beyond reach of his neighbours, until lack of space compelled the hive to give off a swarm. The Frenchman on the contrary, with characteristic impetuosity, leaving the cares of state to the Governor or Intendant, and questions of religion to his priest, plunged at once into the excitement and adventure which, in spite of its hardships, give such an irresistable charm to a half savage life. We find constant endeavours to check this tendency of the population to wander, and edicts which forbid the colonists, even on pain of death, to pursue their hunting excursions for more than a league beyond the settlements. But nature is stronger than laws, and the coureurs des bois were to be found everywhere, and often no doubt where no record of their adventures has been preserved. Only six years after Champlain's expedition, at the time when Quebec could only count fifty inhabitants, we find Sagard, whilst a missionary amongst the Hurons on Lake Simcoe, saying, that the only meat he had tasted for six months was given him by a party of French hunters. If the Celt has marked his progress on this continent by that dash and elan which characterizes him as a soldier, but cannot always resist long continued obstacles, the Anglo-Saxon has equally exhibited the invincible tenacity, which enables him to advance step by step in spite of difficulties, and keep what he gains.

One other remark has been suggested by these enquiries, viz., the extraordinary mutability of nations in the savage state, and the rapidity

404

with which one race supplants another over large areas. When Cartier arrived in the St. Lawrence he described large and permanent Indian villages at Stadacona and Hochelaga; but little more than half a century afterwards, when Champlain visited the same localities, he apparently found few Indians about Quebec, and none permanently settled at Montreal. There may have been some exaggeration in Cartier's account, but the main fact remains, and it may probably be accounted for by the increasing power of the Iroquois, which made those places dangerous abodes, and compelled the tribes, which formerly occupied them, to retreat into the interior. Again, the country north of Lake Ontario is described by Champlain as affording signs of having been formerly extensively cultivated and thickly inhabited, but in his day it was entirely deserted, and only used as a hunting ground by the neighbouring tribes. But the country of the Ottawa, and across to the Northern shore of Lake Huron, as also the Western Peninsula, is described as full of Hurons, and of Algonquin, Ottawa, Nipissing and other allied tribes. Amongst the Hurons alone, in the limited area between Matchedash Bay and Lake Simcoe, he reckons 18 walled villages, numbering 2,000 fighting men, and Sagard puts the whole population down at 30 or 40,000 souls.\* Yet, within 30 years from that time this region was also a desert, and the remnants of the former inhabitants had retreated to the Northern Lakes, and as far west as the Sioux. The Hurons indeed were almost exterminated, and the paltry remnant which had not been either destroyed or incorporated with other tribes, were collected and brought down to Quebec, where their descendants still occupy the village of Lorette. A11 the tribes of the Western Peninsula, and the Eries on the South shore of that Lake, seem also to have been utterly exterminated, as well as the greater part of the Illinois, and other Western tribes and the Iroquois were dominant over all Upper Canada, and all the northern part of New York and Ohio. All this occurred without the intervention of the white man, and there has been no disappearance of a savage race since from the diseases and vices which civilization brings in its train, which has surpassed, even if it has equalled in completeness and rapidity, the desolation which the conquering

<sup>\*</sup> It would not appear that this estimate can have been very greatly exaggerated, from the account given of the missionary establishments. They numbered in their most flourishing period, about 1645, 42 missionaries besides their attendants. Of these two or three only remained at the principal station of Ste. Marie, at the mouth of the Wye, five other villages were called residences, where one or two missionaries remained permanently, and the rest moved from village to village often having as many as 10 under their charge. As several of these villages are mentioned as containing from 100 to 200 cabins, and 4 or 5 families residing in each, the whole population cannot have fallen far short of 30,000.

#### 406 SUPPOSED PREVALENCE OF ONE CRANIAL TYPE

Iroquois spread around them. They too have now nearly vanished from the scene of their former power under other influences, and may soon, like the Eries and Hurons, be remembered only by a name; but when we find such extraordinary vicissitudes occurring during the brief space, of which we have any certain record, we cease to be so much surprized at the total disappearance of the Mound Builders and other prehistoric races.

# SUPPOSED PREVALENCE OF ONE CRANIAL TYPE THROUGHOUT THE AMERICAN ABORIGINES.

BY DANIEL WILSON, LL.D.,

PROFESSOE OF HISTORY AND ENGLISH LITERATURE, UNIVERSITY COLLEGE, TORONTO.

Read before the American Association for the advancement of Science, at Montreal, August 17th, 1857.

Among the various grounds on which Columbus founded his belief in the existence of an undiscovered continent beyond the Atlantic, especial importance was attached to the fact that the bodies of two dead men had been cast ashore on the island of Flores, differing essentially in features and physical characteristics from any known race. When at length the great discoverer of this Western world had set his foot on the islands first visited by him, the peculiarities which marked the gentle and friendly race of Guanahanè were noted with curious minuteness; and their "tawny or copper-hue," their straight, coarse, black hair, strange features, and well-develloped forms, were all recorded as objects of interest, by the Spaniards. On their return the little caravel of Columbus was freighted not only with gold and other coveted products of the new world, but with nine of its natives, brought from the Islands of San Salvador and Hispaniola,-eight of whom survived to gaze on the strange civilization of ancient Spain, and to be themselves objects of scarcely less astonishment than if they had come from another planet. Six of these representatives of the western continent, who accompanied Columbus to Barcelona, where the Spanish Court then was, were baptised with the utmost state and ceremony, as the first fruits offered to heaven from the new found world. Ferdinand and the enthusiastic and susceptible Isabella, with the Prince Juan, stood sponsors for them at the font ; and when, soon after, one of them, who had been retained

in the Prince's household, died, no doubt as to their common humanity marred the pious belief, that he was the first of his nation to enter heaven.

Such was the earliest knowledge acquired by the old world of the singular type of humanity generically designated as the Red Indian; and the attention which its peculiarities excited when thus displayed in their fresh novelty has not yet exhausted itself, after an interval of upwards of three centuries and a half. That certain special characteristics in complexion, hair, form and features, do pertain to the whole race of this continent is not to be disputed; and these prevalent characteristics were so generally noted, to the exclusion of all others, that Ulloa, and after him others of the Spanish explorers of the new world remarked : He who has seen one tribe of Indians, has seen all. In the sense in which this remark was first made, and by Spaniards, who knew only of Central America and the tropical region of the Southern continent, there was nothing in it to challange. But that which was originally the mere rude generalization of a traveller, has been adopted in our own day as a dogma of science ; and the universality of certain homogeneous characteristics of the aboriginal tribes and nations of America, with the exception of the Esquimaux, is assumed as an established postulate for the strictest purposes of scientific induction, and has been repeatedly affirmed in the very words of the Spaniard.

Such authorities as Robertson the historian, and Malte Brun, may be classed along with the first Spanish observers, in the value to be attached to their sweeping generalizations. "The Esquimaux," says the former, "are manifestly a race of men distinct from all the nations of the American continent, in language, in disposition, and in habits of life. But among all the other inhabitants of America there is such a striking similitude in the form of their bodies, and the qualities of their minds, that, notwithstanding the diversities occasioned by the influence of climate, or unequal progress of improvement, we must pronounce them to be descended from one source."\* Malte Brun, with more caution, simply affirms, as the result of a long course of physiological observations, that "the Americans, whatever their origin may be, constitute at the present day a race essentially different from the rest of mankind."+ But greater importance is to to be attached to the precisely defined views of Humboldt, in so far as these are not-like those of so many other writers on this subject.

<sup>\*</sup> Robertson's America, B. IV. In relation to languages, this difference between the Esquimaux and the Indians is no longer maintained.

<sup>+</sup> Malte Brun, Geog. Lib. xxv.

-a mere reproduction of the opinions of Morton. Humboldt remarks in the preface to his *Researches*: "the nations of America, except those which border the polar circle, form a single race, characterized by the formation of the skull, the colour of the skin, the extreme thinness of the beard, and the straight glossy hair."

Very few and partial exceptions can be quoted to the general unanimity of American writers,-some of them justly regarded as authorities in ethnology,-in reference to this view of the nations of the whole American continent, north and south. With the solitary exception of the Esquimaux, they are affirmed to constitute one nearly homogeneous race, varying within very narrow limits from the prevailing type, and agreeing in so many essentially distinctive features, as to prove them a well defined variety, if not a distinct species of the Genus Homo. Prichard, Lawrence, Wiseman, Knox, Squier, Gliddon, Nott, and Meigs, might each be quoted in confirmation of this opinion, and especially of the prevailing uniformity of certain strongly marked cranial characteristics: but the fountain head of all such opinions and views is the justly distinguished author of the Crania Americana, Dr. Morton, of Philadelphia. His views underwent considerable modification on some points relating to the singular cranial conformation observable in certain skulls found in ancient American graves ; especially in reference to the influence of artificial means in perpetuating changes of form essentially different from the normal type; but the tendencies of his matured opinions all went to confirm his original idea of universal approximation to one cranial type throughout the New World. In some of his latest recorded views he remarks, as the result of his examination of a greatly extended series of Peruvian crania :--- "I, at first, found it difficult to conceive that the original rounded skull of the Indian could be changed into this fantastic form; and was led to suppose that the latter was an artificial elongation of a head remarkable for its length and narrowness. I even supposed that the long-headed Peruvians were a more ancient people than the Inca tribes, and distinguished from them by their cranial configuration. In this opinion I was mistaken. Abundant means of observation and comparison have since convinced me that all these variously formed heads were originally of the same rounded shape."

Such are the latest views of Dr. Morton, as set forth in the posthumous paper on *The physical type of the American Indians*, contributed by him to the second volume of Dr. Schooolcraft's "History of the Indian Tribes," and edited for that work by his friend and fellow labourer, John S. Phillips. In that same final contribution to his favourite science. Dr. Morton's matured views on the cranial type of the American continent-based on the additional evidence accumulated by him, in the interval of twelve years which elapsed between the publication of the Crania Americana and the death of its author,are thus defined : " the Indian skull is of a decidedly rounded form. The occipital portion is flattened in the upward direction, and the transverse diameter, as measured between the parietal bones, is remarkably wide, and often exceeds the longitudinal line.\* The forehead is low and receding, and rarely arched as in the other races; a feature that is regarded by Humboldt, Lund, and other naturalists. as a characteristic of the American race, and serving to distinguish it from the Mongolian. The cheek-bones are high, but not much expanded ; the maxillary region is salient and ponderous, with teeth of a corresponding size, and singularly free from decay. The orbits are large and squared, the nasal orifice wide, and the bones that protect it arched and expanded. The lower jaw is massive and wide between the condyles; but, notwithstanding the prominent position of the face, the teeth are for the most part vertical."<sup>+</sup> The views thus set forth by him who has been justly designated : " the founder of the American School of Ethnology,"<sup>‡</sup> have been maintained and strengthened by his successors; and scarcely any point in relation to Ethnographic types is more generally accepted as a recognised postulate than the approximative homogeneous cranial characteristics of the whole American race. A distinction, indeed is made by Morton, and to some extent recognised by his successors, between the barbarous, or American, and the civilized, or Toltecan tribes of the continent : but the distinction, according to their own view, is arbitrary, and appears alike indefinite and unsatisfactory; unless an essential difference of race, corresponding to that which is held to separate the Esquimaux from the true Autochones of America, is acknowledged to exist, whereas this is expressly denied. One of the three propositions with which Dr. Morton sums up the results borne out by the evidence advanced in his Crania Americana is: "That the American nations, excepting the polar tribes, are of one race and one species. but of two great families, which resemble each other in physical, but

VOL. II.-C\*

<sup>\*</sup> In this statement Dr. Morton would seem to have had in view his theoretical type, rather than the results of his own careful observations, unless he accepted as evidence the artificially abreviated and flattened skulls, and even of these his *Crania Americana* furnishes only one exceptional example, from a mound on the Alabama River, (pl. LIV.) "It is flattened on the occiput and os frontis in such manner as to give the whole head a sugar-loaf or conical form, whence also its great lateral diameter, and its narrowness from back to front."

<sup>+</sup> Physical type of the American Indians. Schoolcraft's His., &c., II. p. 316,

<sup>‡</sup> Types of Mankind. p. 87.

differ in intellectual character."\* Any further difficulty, arising from physical differences, is sought to be overcome by the application of the hypothesis that "these races originated in nations, and not in a single pair; thus forming proximate but not identical species."\* But it is not fairly grappled with by any of the writers of "the American School of Ethnology." The closest approximation to a recognition of the legitimate deduction from such contrasting cranial characteristics is made by Dr. Morton himself, where he remarks in reference to the larger cerebral capacity of the Indian in his savage state, than of the demi-civilized Peruvian or ancient Mexican; "Something may be attributed to a primitive difference of stock; but more, perhaps, to the contrasted activity of the two races." It is to be noted, moreover, that Dr. Morton distinctly recognises certain unmistakeable diversities of form into which the assumed American cranial type is subdivided. He thus remarks, in his Crania Americana, under the head: General observations on the barbarous nations composing the American family:--" After examining a great number of skulls, I find that the nations east of the Alleghany Mountains, together with the cognate tribes, have the head more elongated than any other Americans. This remark applies especially to the great Lenapé stock, the Iroquois, and the Cherokees. To the west of the Mississippi we again meet with the elongated head in the Mandans, Ricaras, Assinaboins and some other tribes." But to this, Dr. Morton superadds the further remark: "Yet even in these instances the characteristic truncature of the occiput is more or less obvious, while many nations east of the Rocky Mountains have the rounded head so characteristic of the race, as the Osages, Ottoes. Missouris, Dacotas, and numerous others. The same conformation is common in Florida; but some of these nations are evidently of the Toltecan family, as both their characteristics and traditions testify. The head of the Charibs, as well of the Antilles as of Terra Firma, are also naturally rounded; and we trace this character as far as we have had opportunity for examination through the nations east of the Andes, the Patagonians and the tribes of Chili. In fact, the flatness of the occipital portion of the cranium will probably be found to characterise a greater or less number of individuals in every existing tribe from Terra del Fuego to the Canadas. If their skulls be viewed from behind, we observe the occipital outline to be moderately curved outward, wide at the occipital protuberances, and full

<sup>\*</sup> Crania Americana. p. 260.

<sup>†</sup> Types of Mankind. p. 276.

<sup>‡</sup> Crania Americana. p. 65.

from those points to the opening of the ear. From the parietal protuberances there is a slightly curved slope to the vertex, producing a conical, or rather a wedge-shaped outline." These opinions are still more strongly advanced in Dr. Morton's most matured views, where he ascribes the same characteristics to the Fuegian, the Indian, the tribes to the west of the Rocky Mountains, and those which skirt the Esquimaux on the north. "All possess alike the long, lank, black hair, the brown or cinamon-coloured skin, the heavy brow, the dull and sleepy eye, the full and compressed lips, and the salient but dilated nose. The same conformity of organization is not less obvious in the osteological structure of these people, as seen in the square or rounded head, the flattened or vertical occiput, the large quadrangular orbits, and the low receding forehead;" and he goes on to reiterate the opinion that, in spite of any " mere exceptions to a general rule," the Indian of every variety " is an Indian still, and cannot be mistaken for a being of any other race." Still more, in the same final embodiment of his matured opininions, Dr. Morton affirms the American race to be essentially separate and peculiar, and with no obvious links, such as he could discern, between them and the people of the old world, but a race distinct from all others.

It is obvious that the tendency of Dr. Morton's views, as based on the results of his extended observations, was to regard the most marked distinctions in American crania, as mere variations within narrow limits, embraced by the common and peculiar type, which he recognised as characteristic of the whole continent, both north and south. In this opinion his successors have not only concurred, but they even attach less importance to the variations noted by his careful eye. Dr. Nott, for example, remarks on the peculiarities of the very remarkable brachycephalic skull taken from a mound in the Scioto valley, and figured the natural size in Messrs. Squier & Davis's *Ancient Monuments of the Mississippi Valley*:\* "Identical characters pervade all the American race, ancient and modern, over the whole continent. We have compared many heads of living tribes, Cherokees, Choctaws, Mexicans, &c., as well as crania from mounds of all ages, and the same general organism characterizes each one."\*

One more authority may be quoted to show that the conclusions thus early adopted by Dr. Morton, and maintained and confirmed by his subsequent writings, are still regarded as among the best established and most indisputable summaries deduced from well ascertained data of American Ethnology. Dr. J. Aitken Meigs, the edi-

<sup>\*</sup> Smithsonian Contributions to Knowledge. vol. I. pl. 47.

<sup>†</sup> Types of Mankind. p. 291.

## 412 SUPPOSED PREVALENCE OF ONE CRANIAL TYPE

tor of Dr. Morton's "Catalogue of Skulls," subsequent to the transference of his greatly augmented collection to the Academy of Natural Sciences of Philadelphia, remarks, in his *Cranial Chracteristics of the Races of Men*: "Through *Crania Americana*, it has long been known to the scientific world that a remarkable sameness of osteological character pervades all the American tribes from Hudson's Bay to Terra del Fuego. It is equally well known that the researches of Humboldt and Gallatin have demonstrated a conformity not less remarkable in the language and artistic tendencies of these numerous and widely scattered aborigines."\*

Such, then, is the opinion honestly arrived at by Dr. Morton, as the result of extensive study and observation, accepted and confirmed by his successors, and now made the starting point from whence to advance to still more comprehensive and far-reaching conclusions. It is not necessary, therefore, to prove the universal recognition of this well known Ethnological postulate by further references to recent authorities; but there is one author, at once so distinguished among American men of science, and so peculiar from the point of view from whence he has regarded the entire question of American Ethnology, as to merit special attention. Professor Agassiz, in his Sketch of the Natural Provinces of the Animal World, and their relation to the different Types of Man, re-affirms the homogeneous characteristics and ethnic insulation of the American Indian on entirely novel and independent grounds. After defining the evidence on which the general opinion is based, that the boundaries within which the different natural combinations of animals are circumscribed on the surface of the earth coincide with the natural range of distinct types of man, he proceeds to show that America, including both its northern and southern continent, differs essentially from Europe and Asia, or Africa, in being characterised throughout by a much greater uniformity in all its natural productions, than anything which comparison enables us to trace in the old world. He then adds : "With these facts before us, we may expect that there should be no great diversity among the tribes of man inhabiting this continent; and indeed the most extensive investigation of their peculiarities, has led Dr. Morton to consider them as constituting but a single race, from the confines of the Esquimaux down to the southernmost extremity of the continent. But, at the same time, it should be remembered that, in accordance with the zoological character of the whole realm, this race is divided into an infinite

<sup>\*</sup> Indigenous Races of Men, p, 332.

number of small tribes, presenting more or less difference one from another."

The latest views of Agassiz, as set forth in his contribution to the Indigenous Races of the Earth, present us with the same opinions. advanced with additional confirmation from other data. Passing from the general zoological analogies in the distribution of species, to the special one of the monkey, he remarks on the diversity of opinions among men of science as to the genus Cebus, which some Zoologists recognise as one species, others separate into two or three. while others again subdivide it into as many as ten :--- "Here we have, with reference to one genus of monkeys, the same diversity of opinion as exists among Naturalists respecting the races of man. But in this case, the question assumes a peculiar interest, from the circumstance that the genus Cebus is exclusively American ; for that discloses the same indefinite limitation between its species which we observe also among the tribes of Indians, or the same tendency to splitting into minor groups, running really one into the other, notwithstanding some few marked differences, —in the same manner as Morton has shown that all the Indians constitute but one race, from one end of the continent to the other. . . . . . In the Old World, notwithstanding the recurrence of similar phenomena, the range of variation of species seems less extensive, and the range of their geographical distribution more limited. In accordance with this general character of the animal kingdom, we find likewise that, among men, with the exception of the Arctic Esquimaux, there is only one single race of men extending over the whole range of North and South America, but dividing into innumerable tribes; whilst, in the Old World there are a great many well-defined and easily distinguished races, which are circumscribed within comparatively much narrower boundaries." To this may be added Mr. Gliddon's summary of the views advanced by him, in carrying out the suggestive idea of Agassiz, in the Monogenists and Polygenists of the former :\*-"We may now reconsider," some of the practical issues of this inquiry. It has been shown, 1st. That in America. humatile men and humatile monkeys occupy the same palæontological zones. 2nd. That whilst all such remains of man are exclusively of the American Indian type, the monkeys called Hapale, Cebus, Callithrix, &c., are equally 'terræ geniti' of this continent. . . . . Finally, that permanence of type, as well for humanity as for simiadæ, is firmly established in both genera, from the hour in which we are living

<sup>\*</sup> Indigenous Races of Men, p. 522.

#### 414 SUPPOSED PREVALENCE OF ONE CRANIAL TYPE

back to a vastly remote, if not incalculable era of unrecorded time."

Such being some of the very important and comprehensive deductions now based on the premises originally advanced by Dr. Morton, it becomes of some interest to the Ethnologist to ascertain if these premises are so surely established as to be beyond all question. That some of the assumed evidence of this all-pervading conformity has been adopted on insufficient data, is manifest from the premature generalizations in relation to the holophrastic or polysynthetic character affirmed to pertain to all the languages and dialects of America, and assumed to supply the place of that grammatical unity of structure in the Indo-European languages, the establishment of which has led to such important results.

The dialects of the numerous families of American tongues multiply with the labors of their investigators. Duponceau, writing in 1822, numbered them as one thousand two hundred and fourteen. Scarcely any trace of the roots of a common vocabulary help in the comparison of many of these diverse languages of the New World. Of some of the indigenous tongues even now spoken around the Rios and Colorado, and in more southern latitudes, the holophrastic attribute is rather assumed than known; and in more than one group, of which the Carib is an illustration, languages are found in nearly the lowest stages of undeveloped simplicity. Nevertheless, this holophrastic or polysynthetical mode of condensing a group of words into one abreviated term susceptible of further modification, and of inflexion, is well worthy of the interest it has excited. This distinguishing trait, or "plan of thought of the American languages," as Dr. Lieber has designated it, has yet to be applied as a philological test to many untried tongues and dialects of the new continents ; but meanwhile some of the most comprehensive generalizations based on it seem to have been advanced in the inverse ratio of the linguistic knowledge of their advocates. Those most fitted to pronounce on the subject-as Duponceau, in his later writings, and Gallatin-most cautiously avoid general conclusions, such as the former was tempted to by earlier and less complete observations; and, as in many other inquiries, extended knowledge tends at present to complicate the question, instead of confirming the seductive theory of Duponceau, of a common philological character pervading the languages of America from Greenland to Cape Horn.

The extreme interest which attaches to the investigation of the distinguishing traits already recognized as pertaining to the languages

of the New World, cannot be over estimated, though it is not improbable that an exaggerated value has been assigned to the significance of their specialities. In more than one trait characteristics are recognized common both to Polynesian and African idioms; and further consideration suggests the probability that the special synthetic tendency pertains fully as much to an immature stage of development of these languages, as to any specific individualizing feature born of the New World's insulation. As, moreover, the opinion advanced by Gallatin, after mature investigation, of the correspondence of the Esquimaux language to those of the true Indians of America, in the same degree that these possess elements in common, is acknowledged to be correct: the assumed philological unity of the American Indians amounts to no more than a predominance of certain linguistic tendencies analogous to such as, in the Old World, embrace widely varied ethnic and geographic areas. "Physically," says Latham, " the Eskimaux is a Mongol and Asiatic; philologically he is American, at least in respect to the principles upon which his speech is constructed."\*

The same manifestation of a predisposed tendency to shape the evidence to a foregone conclusion, or to assume as special whatever varies from the Normal type, may be traced in various other lines of argument; such as, for example, where, in proof of the essential ethnic difference between the Esquimaux and the true Indian of America, the traveller Herne is quoted as stating that "the Indian tribes who are their proximate neighbours on the South, once excused an unprovoked massacre of Esquimaux men, women and children, by asserting that they were a people of a different nature and origin from themselves." Such a lire of argument would prove other tribes, besides the Esquimaux, to be of a different nature and origin. Similar evidence, indeed, night suffice to show that the Anglo-Saxons of the ancient Kingcom of Northumbria, so soon as they were separated by the political boundary line of the Sark or Tweed, became essentially different races; for assuredly no Indians and Esquimaux could manifest more deadly hatred to each other than that which intensifies the wild vigor of the old Border Minstrelsy.

But it is not necessary to go beyond the American pale for similar evidences. The Guanches, discovered by Columbus in 1492, attracted his attention by their gentle manners and inoffensive habits, and from them he learned of the Caribs, a fierce and warlike people

<sup>\*</sup> Varieties of Man, p. 290.

of neighbouring islands and the mainland, of whom they lived in constant dread, and who subsequently became familiar to the Spaniards as a ferocious, crafty and revengeful race, delighting in cannibalism.

Moreover, the great Admiral failed not to note the marked distinction between the fair complexion of the Guanches and the reddish olive of the ferocious Caribs. Both Humboldt and Morton acknowledge the existence of considerable varieties in colour and complexion, from nearly white to a dark brown. The latter writer, indeed---guarding against possible deductions from such an admission, adverse to his favourite theory of a universally predominating conformity in all the essential characteristics of the American aborigines----adds : "These differences in complexion are extremely partial, forming mere exceptions to the primitive and national tint that characterises these people from Cape Horn to the Canadas. The cause of these anomalies is not readily explained; that it is not climate, is sufficiently obvious; and whether it arises from partial immigrations from other countries, remains yet to be decided."\*

The stronghold, however, of the argument for the essential oneness of the whole tribes and nations of the American continents, is the supposed uniformity of physiological, and especially of physiognomical and cranial characteristics : an ethnical postulate which has not yet, so far as I am aware, been called in question.

On first visiting the American continent, and enjoying the opportunity of judging for myself of the physical characteristics of the aboriginal race of the forests, I did so under the full conviction of meeting with such a universal approximation to the assumed Normal type, as would fully bear out the deductions of previous observers, and especially of one so persevering in the accumulation of the requisite materials on which to base a legitimate result, as the author of the Crania Americana. I visited Philadelphia with a special view to examine the valuable collection of Crania formed by Dr. Morton, and looked with lively interest on some of the most striking illustrations which it affords, of the typical form assigned by him to the American race. Unfortunately, at that period, (September, 1853,) extensive alterations in progress on the buildings of the Academy, deprived me of the opportunity for such detailed observations as were requisite for drawing any just comparison between these data and the comprehensive deductions founded on them by their collector. When, therefore, I proceeded more recently to open some Indian graves in Canada, and to endeavour to procure crania from others on

<sup>\*</sup> Crania Americna, p. 70.

ascertaining of their disturbance, it was solely with a view to possess myself of one or two specimens of the peculiar American type of cranium, which possessed a special interest to me from its approximation to the ancient brachy-cephalic skull, familiar to me, as found in one important class of early British barrows. It was accordingly, simply with a sense of disappointment that I found the results of repeated efforts, in different localities, supplied me with crania, which, though undoubtedly Indian, exhibited little or no trace of the rounded form, with short longitudinal diameter. so strikingly apparent in the ancient crania of Central America and the Mounds. Appreciating, as I did, the invaluable labours of Dr. Morton-which will be more fully prized, as the important science they tend to elucidate commands a wider attention and more careful study—it did not occur to me at first to question any of the results so frequently reiterted by him, and repeatedly confirmed by the concurrence of later writers. Slowly, however, the idea has forced itself upon me that, to whatever extent the affirmed typical form of the American cranium is found to prevail in other parts of the continent, the crania most frequently met with along the north shores of the great lakes, are deficient in some of its most essential elements.

In order to institute such a comparison as will satisfact o test this question, it is necessary to define the essential requisites of the American type of cranium; for, neither Dr. Morton, nor his successors. have overlooked the fact of some deviation from the supposed normal type, not only occurring occasionally, but existing as a permanent characteristic of certain tribes, including those to which I have more particularly to refer. Dr. Morton, as has been already shown, recognized a more elongated head as pertaining to certain tribes, of which he names the Lenapé stock, the Iroquois, and the Cherokees, to the east of the Alleghany Mountains; and the Mandans, Ricaras, and Assinaboins, to the west. But such elongation he speaks of as a mere slight variation from the more perfect form of the normal skull; and he adds : "even in these instances the characteristic truncation of the occiput is more or less obvious."\* So also Dr. Nott, after defining the typical characteristics of the American cranium, remarks: "Such are more universal in the Toltecan than the barbarous tribes. Among the Iroquois, for instance, the heads were often of a somewhat elongated form, but the Cherokees and Choctaws, who, of all barbarous tribes, display greater

<sup>\*</sup> Crania Americana, p. 69.

aptitude for civilization, present the genuine type in a remarkable degree. My birth and long residence in Southern States have permitted the study of many of these living tribes, and they exhibit this conformation almost without exception. I have also scrutinized many Mexicans, besides Catawabas of South Carolina, and tribes on the Canada Lakes, and can bear witness that the living tribes everywhere confirm Morton's type."\*

We cannot err in taking the very interesting cranium found by Dr. Davis and Mr. Squier in a mound in the Scioto Valley, Ohio, as an example of the true typical head; for it is produced as such by Dr. Nott, in the "Types of Mankind," and is described, in the words of Dr. Morton, in Dr. Meigs's Catalogue of Human Crania, in the collection of the Academy of Natural Science of Philadelphia, issued during the present year by order of the Academy, as : "an Aboriginal American ; a very remarkable head. This is, perhaps, the most admirably-formed head of the American race hitherto discovered. It possesses the national characteristics in perfection, as seen in the elevated vertex, flattened occiput, great interparietal diameter, ponderous bony structure, salient nose, large jaws and broad face. It is the perfect type of Indian conformation, to which the skulls of all the tribes from Cape Horn to Canada more or less approximate." As shown by the front view of this skull it presents no trace of pyramidal conformation.

Of this skull the measurements which involve the most essential typical elements, and so furnish precise materials for comparison, are :--

| Longitudinal  | diamete  | er   | <br> | <br> | <br>6.5  | inches. |
|---------------|----------|------|------|------|----------|---------|
| Parietal      | 46       |      | <br> | <br> | <br>6.   | 66      |
| Vertical      | 66       |      | <br> | <br> | <br>6.2  | **      |
| Intermastoid  | Arch     |      | <br> | <br> | <br>16.  | 66      |
| Horizontal ci | rcumfere | ence | <br> | <br> | <br>19.8 | "       |

So that, in fact the cranium very closely corresponds in its measurements, in length, breadth, and height. Still further it may be noted, on examining the full sized view of the skull, as given by Messrs. Squier and Davis (Pl. XLVII.) that the singular longitudinal abreviation of this skull is nearly all posteriorly. A line drawn through the meatus auditorius externus in profile, parallel to the elevated forehead, divides it into two unequal parts, of which the anterior and posterior parts are nearly in the ratio of two to one. To this type the Ancient Peruvian and Mexican crania unquestionably approximate. Of one of the former, from the Temple of the Sun,

<sup>\*</sup> Types of Mankind, pp. 441.

Pl. XI.) Dr. Morton remarks: "A strikingly characteristic Peruvian head. As is common in this series of skulls, the parietal and longitudinal diameters are nearly the same," viz., longitudinal diameter 6-1, parietal diameter 6. So far, therefore, as such evidence goes it appears to justify the conclusion arrived at by Dr. Morton, that the people represented by the Mound skulls in his possession, "were one and the same with the American race, and probably of the Toltecan branch."\*

The conformity affirmed to exist between the ancient Mexican and Peruvian skulls, and those of the modern barbarous tribes, may also be so far asserted as a partial approximation in relation to some of them, and appears to receive a fuller confirmation when carefully selected examples are referred to; as a sufficient number occur to indicate the occasional reappearance of some of the most striking typical peculiarities. Such reappearance of the extremest typical forms is not, however, peculiar to this continent. I possess measurements of a singular modern (female) skull in the collection of Dr. Struthers of Edinburgh, which reproduces in all its strongest features the ancient British brachy-cephalic head; and I have in view more than one living illustration of the same sort :---one, for example-a gentleman of education and intelligence-with such an elevation of the vertex, flattened occiput, and short longitudinal diameter, as, judging by the eye, would more nearly approach the measurement of the Scioto Mound Cranium, than that of any living Indian I have seen.

Of a similar nature is the correspondence pointed out by Dr. Nott<sup>†</sup> between the Scioto mound skull and that of a Cherokee Chief who died a prisoner near Mobile in 1837. In this example, in so far as can be judged from the comparison of both by drawings in profile without precise measurements, the points of agreement are indisputable, though even here amounting to no more than an approximation. The vertical occiput of the ancient skull—more markedly vertical in the original drawing than in the small copy,—is only partially represented in the other; the square form of the ancient profile in the coronal region, becomes conoid in the modern one; and the intersecting line drawn perpendicularly through the meatus shows a very partial reproduction in the modern example, of the remarkable preponderance of posterior cerebral development, which—if not produced by artificial means—is the most singular characteristic of the ancient head.

<sup>\*</sup> Crania Americana, p. 229.

<sup>†</sup> Types of Mankind, p. 442.

But while acknowledging such approximation of the selected modern Cherokee cranium to the ancient type, neither the legitimate deductions following from this, nor from the other examples referred to by Dr. Nott, appear to bear out his conclusions, that not only that type "is found among tribes the most scattered, among the semicivilized and the barbarous, among living as well as among extinct races ;" but "that no foreign race has intruded itself in their midst, even in the smallest appreciable degree." The examples of Cherokee heads referred to in the Table of Anatomical Measurements in the Crania Americana, in so far as they fairly represent the cranial characteristics of this tribe or nation, seem to indicate that the Mobile Chief is an exceptional case; and this is further borne out by the special example selected by Dr. Morton, and figured in his great work; "The head of a Cherokee warrior who was known in the army by the name of John Waring." The following are its most characteristic measurements, exhibiting such a wide divergence from the normal type, as illustrated in that of the Scioto Mound, as to substitute contrast for comparison :---

| Longitudinal     | diamet   | er   | • • |     | •••   | <br>      | • • |     |     |     |     |     |     | <br>    | <br>   | <br> | 7.2  |
|------------------|----------|------|-----|-----|-------|-----------|-----|-----|-----|-----|-----|-----|-----|---------|--------|------|------|
| Parietal         | 66       |      |     | ••• | • •   | <br>• • • | • • |     |     |     |     |     |     | <br>    | <br>   | <br> | 5.3  |
| $\nabla$ ertical | 66       |      |     | • • | •     | <br>      |     |     |     | • • |     | • • |     | <br>    | <br>•• | <br> | 5.3  |
| Intermastoid     | Arch .   |      |     | ••• |       | <br>      | • • | • • | • • | ••  | • • | ••• | • • | <br>• • | <br>   | <br> | 14.1 |
| Horizontal c     | ircumfer | ence |     | • • | • - • | <br>      |     | • • |     |     | ••• |     |     | <br>    | <br>   | <br> | 19.1 |

In the typical head the longitudinal, parietal, and vertical diameters closely correspond; in this the excess of the longitudinal over the parietal and vertical diameters is such as is rarely exceeded in the modern Anglo-Saxon, or even the longer sub-celtic head. Yet, that such an excess in the longitudinal diameter did not present to the experienced eye of Dr. Morton any striking deviation from the form of the modern Indian head is proved by his noting of this very example: "Nor is there anything remarkable in the form of the skull."

Bearing in remembrance then, the partial nature of the approximation so far apparent between the ancient and modern American cranium; personal observation leads me to believe that such is to be found—with exceptional instances of closer affinities, and also with important divergencies from the typical Indian form and character, not exceptional, but pertaining to the whole nation,—among the still numerous examples of the Algonquin stock, as represented by the Chippeways. Of these I have examined, and compared by the eye, many at widely scattered locations: on Lake Simcoe and the Georgian Bay; at Mackinaw in Lake Huron, and at Sault St. Marie; at

### THROUGHOUT THE AMERICAN ABORIGINES.

Ontonagon, La Point, the Apostle Islands, and the St. Louis River, on Lake Superior; as well as such chance opportunities as occur in the nighbourhood of Niagara Falls, and on the streets of our Canadian towns and villages. Physiognomically they present the wide and prominent mouth, high cheek-bones, and broad face, so universally characteristic of the American Indian; but they by no means present in a remarkable degree the wide and massive lower jaw. which has been noted as of universal occurrence among the Red Indians. Still more noticeable is the absence of the aquiline nose, so characteristic generally of the true Indian in contradistinction to the Esquimaux. The eye may be fully depended on for physiognomical characteristics; it is of much less value in testing variations from any assumed cranial type, especially in reference to comparatively minute divergencies of measurement. Nevertheless, their heads appear to me, to be of short longitudinal diameter, as compared with those of other tribes in part displaced by them; but-in so far as may be judged from the observation of the living head covered with the thickly matted and long coarse hair of the Indian. -they are not remarkable for vertical elevation.

It is by no means an easy thing to obtain actual measurements of Indans' heads. I have found an Indian not only resist every attempt that could be ventured on, backed by arguments of the most practical kind; but on the solicitation being pressed too urgently, he trembled, and manifested the strongest signs of fear, not unaccompanied with anger, such as made a retreat prudent. In other cases where the Indian has been induced to submit his head to examination, his Squaw has interfered and vehemently protested against the dangerous operation. The chief object of dread seems to be lest thereby the secrets of the owner should be revealed to the manipulator; but this rather marks the more definite form of apprehension in the mind of the christianized Indian. With others it is simply a vague dread of power being thereby acquired over them; such as Mr. Paul Kane informs me frequently interfered to prevent his taking the portraits of the Indians of the North-west, unless by stealth.

The following table presents the results of an examination of six pure-breed Chippeways, at the Indian reserve on Lake Couchiching; with the addition of two others, the only examples of the same nation, given by Morton, in the *Crania Americana*. From these it will be seen that, while in the majority of them a certain approximation of the longitudinal to the parietal diameter is discernible, it is of a very partial nature, except in one instance (No. 5) where a manifest

421

correspondence to certain relative proportions of the Mound-builder type of head is apparent:

|                                                                                                                                                                                                                                                                                 | Longitu-<br>dinal<br>Diameter | Parietal<br>Diameter                                                                | Frontal<br>Diameter                                     | Inter-<br>mostóid<br>Arch.                                   | Horizon'l<br>Circum-<br>ference.                             |

TABLE I.-CRANIAL MEASUREMENTS.-(CHIPPEWAYS.)

Some of the measurements in the living head are necessarily affected by the hair, always coarse and abundant with the Indian. Others again, such as the vertical diameter cannot be taken; but the mastoid processes are sufficiently prominent to leave very little room for error in the measurement of the inter-mastoid arch; and this suffices to show the very exceptional approximation of the modern Chippeway head—in so far as it is illustrated by these examples,—to the ancient type, in the proportional elevation of the vertex. In the horizontal circumference some deduction must be made for the hair, to bring it to the true cranial measurement in all the six living examples.

I have selected the Chippeways for reference here, because —taking the above measurements, along with other observations, —they appear to indicate a nearer approach to some of the assumed characteristics of the American cranial type, in this widely spread branch of the Indian stock, than is observable in other Northern races, and especially than is apparent on an examination of skulls belonging, as I believe, to the original Huron occupants of the greater part of the country around Lakes Simcoe and Couchiching, where the Chippeways more especially referred to are now settled, including Upper Canada, when first explored.

But the divergent characteristics noticeable in these, and still more in the crania of older Canadian graves, are by no means confined to those named, as a few examples will suffice to show. Such a radical divergence from the assumed normal type as has been already noted in Dr. Morton's selected Cherokee cranium, is no less obvious in that of the Miami,—the head of a celebrated chief, eloquent, of great bravery, and uncompromising hostility to the Whites: (*Crania Americana*, p. 182.)

| Longitudinal Diameter    | 7.3  |
|--------------------------|------|
| Parietal Diameter        | 5.5  |
| Vertical Diameter        | 5.5  |
| Inter-mastoid Arch       | 14.5 |
| Horizontal Circumference | 19.8 |

In the example of the Potawatomies, "A skull of a genuine Potowatomie, remarkable for its capacity behind the ears:" (Ibid p. 186.)

| Longitudinal Diameter    | 7.8  |
|--------------------------|------|
| Parietal Diameter        | 5.7  |
| Vertical Diameter        | 5.3  |
| Intermastoid Arch        | 16.0 |
| Horizontal Circumference | 22.1 |

In that of the Blackfeet, the largest of two brought to Philadelphia by Catline, and noted by Dr. Morton for its great breadth between the parietal bones. It is also very markedly pyramidal. Nevertheless, here also the longitudinal diameter is nearly two inches in excess both of the parietal and vertical diameters : (Ibid, 202.)

| Longitudinal Diameter    | 7.1  |
|--------------------------|------|
| Parietal Diameter        | 5.4  |
| Vertical Diameter        | 5.1  |
| Inter-mastoid Arch       | 13.8 |
| Horizontal Circumference | 19.9 |

So also Dr. Morton says of the Menominees: "I have received a series of Menominee skulls, embracing eight specimens. They are something larger than the average of Indian crania; and although for the most part they present a *rather oval shape*, they are all marked by a gently flattened occiput." (Ibid. 179.) A reference to the Catalogue of the Morton Collection at Philadelphia discloses the important fact that of those marked by the shorter longitudinal diameter, Nos. 35, 44, and 563, are females.

Again of the Delawares he remarks: "The few Delaware skulls in my possession are more elongated than is usual in the American tribes; they are also narrower in proportion in the parietal diameter and less flattened on the occiput."

Such are some indications of data-derived from a source altogether unexceptionable in the present argument, ---which seem to render it impossible to uphold the views so repeatedly affirmed, of the physiognomical, physiological, and above all, the cranial unity characterizing the whole ancient and modern aborigines of the New World.

I omit. meanwhile, any reference to the characteristics ascribed by Dr. Morton to the Iroquois and Hurons or Wyandots : those tribes to whom, with the greatest probability, may be assigned the crania specially examined by me, found along the shores of Lake Ontario, the north shore of Lake Erie, and on Lake Huron. When Champlain effected permanent settlements on the Lower St. Lawrence in 1608, he found the north shores of the river occupied, below Quebec, by the Montagnets or Montagnards, and above it by the Ottawas, and other branches of the Algonquin stock. The country to the westward, constituting the great Canadian Peninsula lying between Georgian Bay, the Lakes Huron, Erie, and Ontario, was chiefly, if not entirely, in the possession of the Hurons ; while the Iroquoisto whom the latter were most nearly allied in social and physical characteristics, though at deadly enmity with them,-occupied the south bank of the St. Lawrence, and had their chief villages scattered among the clustering lakes, and the rivers, on the southern shore of Lake Ontario, which they continued to occupy and cultivate till driven out or exterminated in the revolutionary wars. The Iroquois and the Huron tribes were alike distinguished from many others, and especially from the neighbouring hunter tribes of the Algonquin nations, by considerable attention to cultivation, and by living permanently in large settled villages. But the Iroquois Wars effectually arrested the progress of agriculture, and at length eradicated or drove out the Hurons from their country between Georgian Bay and Lake Ontario, where they were replaced by rude Algonquin tribes formerly lying to the north of them.

The Hurons then, and, in very modern years, the Algonquins, but more especially the former, are the occupants of the country immediately to the north of Lakes Erie and Ontario, whose remains are to be looked for in the Indian graves of this district. Of them Latham remarks : "The Iroquois and Algonkins exhibit in the most typical form the characteristics of the North American Indians, as exhibited in the earliest descriptions, and are the two families upon which the current notions respecting the physiognomy, habits, and moral and intellectual powers of the so-called Red Race are chiefly founded."\* In many respects, however, they presented a striking contrast. The Algonquin stock, represented by the modern Chippeways, is only known to us as embracing rude and savage hunter tribes ; and both

<sup>\*</sup> Varieties of Mankind. p. 333.

physically and intellectually the Chippeways were inferior to the Iroquois and Hurons. The latter displayed a manifest aptitude for civilization. In war they repeatedly effected and maintained extensive and powerful combinations. Their agricultural operations gave proof of a systematic and continuous cultivation of the soil. Corn especially was grown to a great extent. Tobacco also was so extentensively cultivated by one of the tribes of Upper Canada as to lead to its designation by the French Jesuit Missionaries of the seventeenth century as the Petunians, or Tobacco Growers. Moreover, their knowledge and practice of agriculture appears to have originated independently of all European influence; and but for their fatal involvement in the struggle between the Colonists and the representatives of the mother country, there seemed a reasonable prospect of such an Iroquois civilization being developed in the western districts of the State of New York, as might have enabled these representatives of the ancient owners of the soil to share in the gradual advancement of European arts and progress instead of being trodden under heel in the march of civilization.\*

Of Indian skulls dug up within the district once pertaining to the Huron or Wyandot branch of the Iroquois stock, I had observed and cursorily examined a considerable number before my attention was especially drawn to the peculiar characteristics now under consideration, owing to my repeated rejection of those which turned up, as failing to furnish specimens of the assigned typical American head. Since then I have carefully examined and measured twenty-nine Indian skulls, with the following results:

1. Only three exhibit such an agreement with the American type, as judged by the eye, to justify their classification as true brachycephalic crania. One of these (No. 11,) a very remarkable and massive skull, was turned up at Barrie, on Lake Simcoe, with, it is said, upwards of two hundred others. It differs from all the other Indian crania in exhibiting the vertical occiput so very strikingly, that, when laid resting on it, it stands more firmly than in any other position. Of the Scioto Valley cranium, Dr. Morton remarks, in reference to the occiput, "Similar forms are common in the Peruvian tombs, and have the occiput, as in this instance, so flattened and vertical, as to

<sup>\*</sup> La Hontan estimated the Iroquois, when first known to Europeans, at 70,000. At the present time they number about 7,000, including those in Canada; and they still exhibit traces of the superiority which once pertained to them in comparison with other Indian tribes. The very name of a Mohawk still fills with dread the lodges of the Chippeways; and the Algonquin Indians settled on the Canadian reserves on Lake Couchiching and Rice Lake, have been known repeatedly to desert their villages and camp out in the woods, or on an island, from the mere rumor of a Mohawk having been seen in the vicinity.

give the idea of artificial compression; yet this is only an exaggeration of the natural form, caused by the pressure of the cradle-board in common use among the American nation." I think it extremely probable that further investigation will tend to the conclusion that the vertical or flattened occiput, instead of being a typical characteristic. pertains entirely to the class of artificial modifications of the natural cranium familiar to the American Ethnologist alike in the disclosures of ancient graves, and in the customs of widely separated living tribes. In this I am further confirmed by the remark of Dr. Morton, in reference to the Peruvian crania: "These heads are remarkable, not only for their smallness, but also for their irregularity, for in the whole series in my possession, there is but one that can be called symmetrical. This irregularity chiefly consists in the greater projection of the occiput to one side than the other, showing in some instances a surprising degree of deformity. As this condition is as often observed on one side as the other, it is not to be attributed to the intentional application of mechanical force; on the contrary, it is to a certain degree common to the whole American tribes, and is sometimes, no doubt, increased by the manner in which the child is placed in the cradle."\* To this Dr. Morton subsequently added the further remark, in describing an unsymmetrical Mexican skull : " I had almost omitted the remark, that this irregularity of form is common in, and peculiar to American crania."+ The latter remark, however, is too wide a generalization. I have repeatedly noted the like unsymmetrical characteristics in the Brachycepalic crania of the Scottish Barrows, and it has occurred to my mind, on more than one occasion, whether such may not furnish an indication of some partial compression, dependent, it may be, on the mode of nurture in infancy, having tended, in their case also, if not to produce, to exaggerate the short longitudinal diameter, which constitutes one of their most remarkable characteristics. In the case of the Barrie skull, there can be little doubt that the flattened occiput is the result of artificial compression, of a much more decided nature than that of the cradle-board of the papoose.

It is not undeserving of notice here, that the example selected by Cuvier, among his "crania pertaining to the four principal types of the human species," to illustrate the American race, exhibits a strikingly marked prolongation of the occiput. It is described as: "Crâne trouvé dans une caverne, près du Village de Maïpuré près des

<sup>\*</sup> Crania Americana, p. 115.

<sup>†</sup> Types of Mankind, p. 444.

bords de l'Orénoque ; rapporté par M. de Humboldt ;"\* and so far suffices to indicate in how far the opinion already quoted from Humboldt's *Researches* coincides with his own independent observations.

2. In addition to what has been above remarked in reference to the probable artificial origin of the supposed typical form of occiput, assigned by Dr. Morton to the whole American race; I am struck, in the majority of the examples examined, with the total absence of any approximation to the flattened occiput. Fifteen of the crania referred to exhibit a more or less decided posterior projection of the occiput, twelve of these being markedly so, and seven of them presenting such a prolongation of it, as constituted one of the most striking features in one class of ancient Scottish crania, which chiefly led to the suggestion of the term Kumbecephale,<sup>+</sup> as a distinctive term for them.

3. The tendency to the pyramidal form, occasioned by the angular junction of the parietal bones, is apparent in the majority of the skulls examined. I have noted its occurrence more or less prominently in fourteen crania, of which five exhibit a strongly marked pyramidal form, extending to the frontal bone. In some, however, it is only slightly indicated, while in several it is totally wanting.

4. I am further struck with the frequency of the very partial projection, and in some examples the total absence of the supercilliary ridge, a characteristic which I am not aware has been noted before. In seven of the skulls carefully noted by me, this is particularly manifest, and along with their pyramidal vertex and predominant longitudinal diameter, suggest affinities hitherto overlooked, with the Esquimaux form of skull.

5. I would also note that, whereas Dr. Morton states, as the result of his experience, that the most distant points of the parietal bones are, for the most part, the protuberances, I have only found such to be the case in two out of twenty-nine Canadian skulls. The widest parietal measurement is generally a little above the squamous suture.

6. The occurrence may also be noted in several of these crania, of wormian bones of such regularity of form and position, as to constitute indications at least, seemingly confirmatory of the supposed tendency to the development of an *interparietal* or *superoccipital* bone, first pointed out by Dr. Bellamy. This, which is a permanent cranial characteristic in some of the mammalia, is regarded

<sup>\*</sup> Cuvier: Le Régne Animal. Races Humaines, planches 1 et 2. pl. 8. fig. 2.

<sup>+</sup> Prehistoric Annals of Scotland, p. 109.

428

by Dr. Tschudi as an osteological feature peculiar to the Peruvians, and is, he affirms, traceable in all the skulls of that race.

\* TABLE II.-CRANIAL MEASUREMENTS.-WESTERN CANADA, (HURONS.)

The table of measurements of skulls procured from Indian cemeteries to the north of Lakes Erie and Ontario, (Table II.) supplies some, at least, of the elements essential to the formation of a sound judgment on the question under consideration. It embraces twentynine examples. To these I have added, in another table, (Table III.) the corresponding measurements of the skull of the celebrated Mohawk Chief, Joseph Brant, (Tayendanaga,) from a cast taken on the opening of his grave, at the interment of his son, John Brant, in 1852. I have also further added, from the *Crania Americana*, the Iroquois and Huron examples given there, which, it will be seen, agree in the main with the results of my own independent observations; while a comparison of the two tables will be satisfactory to those who may, not unnaturally, hesitate to adopt conclusions, based

<sup>•</sup> Table II.—Of the crania referred to in this Table, Nos. 1 to 9 and No. 29, are in my own possession. Nos. 10, 11, in the Museum of the Canadian Institute. Nos. 12, 13, Museum of Toronto University. No. 14, Museum of Knox's College, Toronto. Nos. 15 to 21, in the collection of Dr. Hodder, Toronto. Nos. 22 to 25, Museum of Trinity College, Toronto. No. 26, in the possession of Rev. John Gray, Orillia. Nos. 27, 28, in the collection of Professor Bovell, M.D., of Trinity College, Toronto.

on the amount of evidence produced, adverse to opinions re-affirmed under such various forms by so high an authority as Dr. Morton, and adopted and made the basis of such comprehensive inductions by his successors.

TABLE III.-CRANIAL MEASUREMENTS.-SIX NATIONS.

The intimate relations in language, manners, and the traditions of a common descent, between those Northern and Southern branches of the Iroquois stock, render these two tables, in so far as they present concurrent results, applicable as a common test of the supposed homogeneous cranial characteristics of the aboriginal American, in relation to the area of the great Lakes. Twenty-nine skulls, such as the first table supplies, or thirty-six as the result of both, may, perhaps, appear to be too small a number on which to base conclusions adverse to those promulgated by an observer so distinguished and so persevering as Dr. Morton, and accepted by writers no less worthy of esteem and deference. Still more may these data seem inadequate, when it is remembered that Dr. Morton's original observations and measurements embraced upwards of three hundred American skulls. But-in addition to the fact that the measurements now supplied, are only the more carefully noted data which have tended to confirm conclusions suggested by previous examinations, in a less detailed manner, of a larger number of examples-an investigation of the materials which supplied the elements of earlier inductions, will show that only in the case of the ancient "Toltecan" tribes did Dr. Morton examine nearly so many examples; while, in relation to what he designated the "Barbarous Race," to which the Northern tribes belong, even in Dr. Meigs' greatly enlarged catalogue of the Morton Collection, as augmented since his death, the Seminole crania present the greatest number belonging to one tribe, and these only amount to sixteen.

In contrast to the form of head of the true American wave, Dr. Morton appends to his *Craniu Americana* drawings and measurements

of four Esquimaux skulls, familiar to me, if I mistake not, in the collection of the Edinburgh Phrenological Society. In commenting on the views and measurements of these, he remarks: "The great and uniform differences between these heads and those of the American Indians will be obvious to every one accustomed to make comparisons of this kind, and serve as corroborative evidence of the opinion that the Esquimaux are the only people possessing Asiatic characteristics on the American continent." In some respects this is undoubtedly true; the prognathous form of the superior maxilla. and the very small development of the nasal bones, especially contrast with well known characteristics of the American aborigines. But having had some little familiarity in making comparisons of this kind, it appears to me, notwithstanding these distinctive points, that an impartial observer might be quite as likely to assign even some of the examples of Iroquois and other northern tribes figured in the Crania Americana, to an Esquimaux, as to a Peruvian, Mexican, or Mound-Builder type. Compare, for example, the vertical and occipital diagrams, furnished by Dr. Morton, of the Esquimaux crania (p. 248) with those of the Iroquois and Hurons (pp. 192-194). Both are elongated, pyramidal, and with a tendency towards a conoid rather than a flattened or vertical occipital form; and when placed alongside of the most markedly typical Mexican or Peruvian heads, the one differs little less widely from these than the other. The elements of contrast between the Hurons and Esquimaux are mainly traceable in the bones of the face: physiognomical, but not cerebral.

Taking once more their cranial measurements as a means of comparison; these, when placed alongside each other, equally bear out the conclusions already affirmed. For comparison, I select, in addition to the Scioto Valley Mound-Builder, the following, as those pointed out by Dr. Morton's own descriptions as among the most characteristic he has figured : Plate XI. Peruvian from the Temple of the Sun: "a strikingly characteristic Peruvian Head." Plate XI, C. "Here again the parietal and longitudinal diameter are nearly equal. The posterior and lateral swell of this cranium are very remarkable, and the vertex has the characteristic prominence." Of the Mexican skulls Dr. Morton remarks, of Plate XVII: "with a better forehead than is usual, this skull presents all the prominent characteristics of the American race,-the prominent face, elevated vertex, vertical occiput, and the great swell from the temporal bones upward ;" and of Plate XVIII : " a remarkably well characterised Toltecan head, from an ancient tomb near the city of Mexico."

TABLE IV .- COMPARATIVE CRANIAL MEASUREMENTS.

If the data which this table supplies furnish any fair illustration of the cranial measurements of the different nations selected, it is scarcely possible to avoid the conclusion, that-in so far as this test is to be relied on,-if a line of separation is to be drawn, it cannot be introduced, as heretofore, to cut off the Esquimaux from all others, but must rather group the Iroquois with them, on the one side, while the Toltecans and the Mound-builders stand as the representatives of a diverse class, on the other. These examples I refer to in preterence to those derived from other sources, or presented in the previous table as the result of my own observations, as they are necessarily unbiassed. They are the specimens of the very races referred to, selected or brought by chance under the observation of Dr. Morton, and included as the characteristic or sole examples in his great work. But the same conclusions are borneout by the examples obtained within the Canadian frontiers; and they seem to me to lead inevifably to this conclusion: that if crania measuring in some cases, two inches in excess in the longitudinal over the parietal and vertical diameters, and in others nearly approximating to such relative measurements.--without further reference here to variations in occipital conformation,-if such crania may be affirmed, without challenge, to be of the same type as others where the longitudinal, parietal, and vertical diameters vary only by small fractional differences, then the distinction between the brachycephalic and the dolichocephalic type of head is, for all purposes of science, at an end, and the labours of Blumenbach, Retzius, Nilsson, and all who have trod in their footsteps have been wasted in pursuit of an idle

431

fancy. If differences of cranial conformation of so strongly defined a character, as are thus shown to exist between various ancient and modern people of America, amount to no more than variations within the normal range of a common type, then all the important distinctions between the crania of ancient European barrows, and those of living races amount to little; and the more delicate details, such as those, for example, which have been supposed to distinguish the Celtic from the Germanic cranium; the ancient Roman from the Etruscan or Greek; the Sclave from the Magyar or Turk; or the Gothic Spaniard from the Basque or Morisco, must be utterly valueless.

For the purpose of testing the assumed predominance of one uniform cranial type throughout the whole American area south of the Arctic circle, by a comparison of measurements of ancient and modern skulls : with those of the exceptional Arctic American, the Esquimaux measurements given by Dr. Morton, have been placed alongside of the others derived from the Crania Americana, in table IV. Through the obliging courtesy of Dr. J. Aitken Meigs, however, I am enabled to present the following table, embracing measurements of fourteen Esquimaux skulls, with one exception, in the collection of the Academy of Natural Sciences of Philadelphia, to which they have been added since Dr. Morton's death. Seven of these. Nos-200, 674,-679, were procured at Godhavn, Disco Island, on the coast of Greenland, by Dr. B. Vreeland, U.S.N. Five of them, Nos. 1558,-1562, were obtained from different localities and ancient graves or cairns, by the lamented Arctic voyager, Dr. E. K. Kane. No. 1563, from the Danish Settlement at Upernavick, was presented to the Academy by Dr. S. W. Mitchell; and the remaining example (A.) is added from a private source. The measurements in this table differ in some respects from the previous ones. The fractions are here sixteenths, instead of tenths. The parietal diameter in the previous tables indicates the extreme breath of the skull between the parietal bones; in this it is invariably taken between the parietal protuberances. In lieu of the mastoid processes, the meati are here selected as yielding measurements of more unvarying uniformity and precision; though they have the disadvantage of being less applicable to comparisons with the living head. Bearing these variations in view, the following table presents additional means for instituting comparisons between the Indian and Esquimaux cranium; and also supplies some valuable data for testing the characteristics of the Esquimaux skull. This Dr. Meigs describes as "large, long, nar-
row, pyramidal; greatest breadth near the base; sagittal suture prominent and keel like, in consequence of the junction of the parietal and two halves of the frontal bones; proportion between length of head and height of face as 7 to 5 .... forehead flat and receding ; occiput full and salient; face broad and lozenge-shaped, the greatest breadth being just below the orbits; malar bones broad, high, and prominent, zygomatic arches massive and widely separated : nasal bones flat, narrow, and united at an obtuse angle, sometimes lying in the same place as the naso-maxillary processes."\* The remarks of Mr. J. Barnard Davis on the last named peculiarities, are worthy of note. In the Esquimaux of the eastern shores of Baffin's Bay, he observes, the nasal bones are scarcely broader, though frequently longer than in some Chinese skulls, where they are so narrow as to be reduced to two short linear bones. "In those of the opposite, or American shores of Baffin's Bay they are very different, presenting a length, breadth, and angle of position, almost equal to those of European races, having aquiline noses." + This slight yet striking anatomical difference seems to supply a link of considerable value as indicative of a trait of physiognomical character in the more southern Esquimaux, tending,-if confirmed by further observation,-like other physical characteristics already noticed, to modify the abrupt transition assumed heretofore as clearly defining the line of separation between the contrasting Arctic and Red Indian races of the New World.

TABLE V.-CRANIAL MEASUREMENTS.-ESQUIMAUX.

In the above table the great length and nacrowness of the Esquimaux skull is abundantly apparent, with no very remarkable elevation of the crown. A comparison, however, with the corresponding

\* Catalogue of Human Crania, A.N.S., 1857, p. 50. † Crania Britannica, p. 30.

## 434 CRANIAL TYPE THROUGHOUT THE AMERICAN ABORIGINES.

measurements in Table II.—keeping in remembrance the difference in the values of the fractions,—will bear out the analogies already indicated, and add new proof that the supposed uniformity traceable throughout this continent, is no more than might fairly be looked for among nations placed to so great an extent under the operation of similar conditions of social life, and affected by so many corresponding extraneous influences.

If external circumstances or the progress of civilization, exercise any influence on physical form, a greater diversity of conformation is to be looked for in Europe than among the Indians of America, where—as in Africa—nearly the same habits and modes of life have characterised the whole "Barbarous Race," throughout the centuries during which Europe has had any knowledge of them. But, making full allowance for such external influences, it seems to me—after thus reviewing the evidence on which the assumed unity of the American race is founded,—little less extravagant to affirm of Europe than of America, that the crania every where and at all periods have conformed, or even approximated, to one type.

As an hypothesis, based on evidence accumulated in the *Crania Americana*, the supposed homogeneity of the whole American aborigines was perhaps a justifiable one. But the evidence was totally insufficient for any such absolute and dogmatic induction as it has been made the basis of. With the exception of the Ancient Peruvians, the comprehensive generalizations relative to the Southern American continent strangely contrast with the narrow basis of the premises. With a greater amount of evidence in reference to the Northern continent, the conclusions still go far beyond anything established by absolute proof; and the subsequent labors of Morton himself, and still more, of some of his successors, seem to have been conducted on the principle of applying practically, and in all possible bearings, an established and indisputable scientific truth, instead of testing by further evidence a novel and ingenious hypothesis.

Dr. Latham, after commenting on the manifest distinctions which separate the Esquimaux of the Atlantic from the tribes of the American aborigines lying to the south and west of them, as elements of contrast which have not failed to receive full justice, adds: "It is not so with the Eskimos of Russian America, and the parts that look upon the Pacific. These are so far from being separated by any broad and trenchant line of demarcation from the proper Indians or the so-called Red Race, that they pass gradually into it; and that in respect to their habits, manner, and appearance, equally. So far is this

the case that he would be a bold man who should venture in speaking of the southern tribes of Russian America, to say: here the Eskimo area ends, and here a different area begins."\* The difference thus pointed out may be accounted for, to a considerable extent, by the diverse geographical conformation of the continent, on its eastern and western sides, which admit in the latter of such frequent and intimate intercourse as is not unlikely to lead to an intermixture of blood, and a blending of the races, however primarily distinct and diverse. The evidence presented here, however, refers to tribes having no such intercourse with the Esquimaux, and distinguished from them by many important characteristics, in manners, social habits, and external physiognomy. Nevertheless if these conclusions, deduced from an examination of Canadian crania, are borne out by the premises and confirmed by further investigation, this much at least may be affirmed: that a marked difference distinguishes the Northern tribes, now or formerly occupying the Canadian area, in their cranial conformation, from that which pertains to the aborigines of Central America and the southern valley of the Mississippi ; and that in so far as the Northern differ from the Southern tribes, they approximate more or less, in the points of divergence, to the characteristics of the Esquimaux :----that intermediate ethnic link between the Old and the New World, acknowledged by nearly all recent ethnologists to be physically a Mongol and Asiatic, if philologically an American.

# ON ATOMIC CONSTITUTION AND CRYSTALLINE FORM AS CLASSIFICATION CHARACTERS IN MINERALOGY.<sup>+</sup>

BY PROFESSOR CHAPMAN, PROFESSOR OF MINERALOGY AND GEOLOGY, UNIVERSITY COLLEGE, TORONTO.

The difficulties that beset the framing of a satisfactory classification in Mineralogy are altogether unknown in other departments of Natural Science. These difficulties originate essentially in the compound nature of minerals, or, in other words, in the apparent absence of corelation between the chemical and physical characters of these bodies. So long as we are forced to admit the existence of dimorphous substances—so long as chemistry remains unable to distinguish or

<sup>•</sup> Varieties of Man, p. 291.

<sup>&</sup>lt;sup>†</sup>Abridged from a paper read before the Montreal Meeting of the American Association for the Advancement of Science.

individualize these—so long must the physical nature of the mineral embodiment claim to be considered, and to be considered prominently, in the classification. The time is now altogether departed when calcite and iron-spar, for example, were held to be less nearly related than calcite and arragonite.

But if this truth be now almost universally admitted, there seems to be a strong tendency in its application to make all characters subservient to two: atomic constitution on the one hand, and crystalline form on the other; and to force these into corelation, by the assumption of various arbitrary and scarcely consistent principles. I do not, of course, intend to deny the high value of these characters, considered generally; but I feel warranted in asserting that, by their arbitrary employment, to the exclusion of other considerations, many really unphilosophical groupings are so concealed under an apparently philosophical garb, as seriously to retard the proper progress of the science.

That mere agreement of crystalline form—even in minute angular measurements, planes of composition, &c.—is really in many instances of no greater value as a classification-character than similarity of hardness or lustre, is necessarily forced upon us, to cite but a single case, by the crystalline identity of borax with augite. That the identity in question may be explained, perhaps, not only here but in other cases, by reference to atomic volume, does not in any way invalidate our argument. Borax and augite, alike in crystalline form, are, when viewed as minerals, when considered in their entire relations, altogether dissimilar. Hence, if two minerals happen to exhibit the same forms and combinations, with corresponding angles, &c., they are not solely on that account to be placed in the same classification group, because, as shewn in the example just referred to, in all their other relations their essential mineral relations—they may stand most widely apart.

Atomic constitution, on the other hand—even if we shut our eyes to the fact of its arbitrary and unsettled character—is of no greater value. Minerals may be assumed to possess, wholly or in part, the same atomic constitution, and yet be utterly opposed in habitus, in conditions of occurrence, in all in fact that constitutes their mineral embodiment. Subdivisions, consequently, founded on this principle, become most artificial. Iron pyrites, for example, is commonly considered to be represented by the formula  $FeS^2$ , whilst in magnetic pyrites and in copper pyrites we have, as one of the constituents, the compound  $Fe^2S^3$ . A sesqui-sulphide ( $Sb^2S^3$  or  $As^2S^3$ ) is also present (according to the received opinion) in the red silvers, zinkenite, &c. ; but who will for a moment maintain that copper pyrites (to say nothing of magnetic pyrites) is not more closely related, in every essential respect as a mineral, to iron pyrites, than to these latter substances. It is utterly impossible not to admit this. Nevertheless. if we blindly follow the chemical view, we are actually forced to maintain the contrary. In the well-known Krystallo-chemische System of Gustav Rose, for example-a system held up by many as a perfect model—magnetic and copper pyrites are not only widely separated from iron pyrites, but they are placed in the same general division with the red silvers, zinkenite, jamesonite, &c. And, in like manner, the carbonates and titaniates, the silicates and sulphates, &c., stand together, from the assumed constitution of their respective acids. Arrangements of this kind may be to a certain extent convenient, but who will venture to call them anything more. Natural classifications akin to those of the botanist and zoologist, most assuredly they are not. Although opposed to my earlier belief, I now feel confident that a satisfactory classification of minerals will never be accomplished until the mineralogist cease altogether the attempt to force his groupings into corelation with the present views of Chemistry. Let it not be forgotten, that Mineralogy has in more than one instance, when in seeming opposition to Chemistry, led the chemist to the adoption of new principles by which the harmony of the two sciences has been maintained; and hence it may be legitimately inferred that, if the mineralogist proceed fearlessly to classify the objects of his study without regard to the restrictions which Chemistry would set before him, further means of agreement will be found to reconcile any differences that may spring up from this independent method of procedure. At present, Chemistry is to the mineralogist, in many respects, a tyrant the most absolute, compelling him by its exactions to groupings in which natural analogies have not the slightest voice. If two compounds have the same representative formulæ, or if amongst binary compounds of oxygen or sulphur, for example, the basic elements happen to be isomorphous or otherwise related in the simple state. they must be placed in the same group, no matter how loudly their physical characters and general conditions of occurrence may exclaim against it. In this manner, in a mineral classification beyond comparison the most philosophical in its general features yet arrived at, we have the unavoidable union of carbonic acid gas with sassolin (hydrated boracic acid) and quartz : the three occurring together, as binary oxygen compounds, the respective bases of which (carbon, boron, silicon,) happen in the simple state to be of a kindred nature. In the system of Gustav Rose again, arsenic acid and iron-glance are placed in the same group, simply because the two are sesqui-oxygen compounds ; a collocation permissible, perhaps, in the case of sesqui-

oxide of iron and arsenic acid as laboratory or chemical products, but certainly without value as regards the occurrence of iron-glance and arsenic acid in their conditions as minerals-in relation to which the following leading truth cannot be too strongly insisted on, viz. ; that chemical compounds and minerals are two and distinct; frequently, at least, if not always so. In the vast majority of cases, the products obtained by the chemist from a given mineral are not in the same condition as that in which they existed prior to their separation, and hence are not, when properly considered, the same bodies. Allowing, first of all, that bodies in combination preserve their atomic constitution unchanged, does it necessarily follow that they preserve their actual physical conditions, or what we may call their normal state of occurrence? Carbonic acid, water, &c., if present as such in solid bodies, must evidently be present in some physical condition altogether unknown to us. Amongst simple bodies also, oxygen, chlorine, &c.. may be said to follow a similar law; and hence we are not justified in reasoning upon the nature of compound bodies from the nature of their constituents when uncombined. But it may also be fairly inferred, that compound bodies in combination do not always retain the atomic constitution which they are assumed to possess in the simple state ; and if so, the formulæ by which we are accustomed to represent these combinations may be absolutely false, and thus worse than valueless, because leading to groupings of an artificial and arbitrary character. When we place cinnabar in the same group with galena, or, on account of the hexagonal crystallization, in a sub-group with millerite and arsenical nickel (kupfer nickel), for example, we know that by the test of the botanist and zoologist our collocation must be pronounced a faulty one: but we defend it on the plea that these minerals are each and all simple binary combinations of a metal with sulphur or with arsenic, exhibiting the general formula RS or RAs. But then the question arises-can we be quite sure of this? And so ultimately we find ourselves obliged to confess that, after all, our knowledge is limited to the fact (if fact it really be,) of the existence in these minerals of equal atoms of base and electro-negative element. This. however, does not necessarily exact for cinnabar the formula HgS. The real formula may be  $Hg^2S + HS^2$ . It is true that this latter compound HgS<sup>2</sup> has not yet been obtained in the laboratory, but analagous compounds of silver and copper (metals considered by Kühn and other chemists to be closely related to mercury,) exist, and whilst various recognized bodies still remain unisolated, the existence of the compound in question cannot be considered entirely hypothetical. At the same time I would not be understood to deny that HgS

### DIVISION OF ROCKS INTO HURONIAN AND LAURENTIAN. 439

may not be the true formula of cinnabar, because, even if such be the case, the peculiar character of the mineral may be accounted for by the not improbable assumption, that the mercury is present in some allotropic condition, essentially different from the normal state of mercury as known to us in its isolated aspect.

In the much-studied division of the silicates, we have a further proof of the really indefinite nature of our present formulæ, and consequently of the uncertain value of the groups founded on this consideration. For example:  $Al^2O^3$  replaces SiO<sup>3</sup> in certain augites and hornblendes. Also, most probably, in staurolite, sillimanite, &c., and perhaps to a certain extent in some spinels and sapphires. On the other hand it is now universally allowed, that in the generality of silicates the formulæ are often greatly simplified by placing the  $Al^2O^3$  among the monatomic bases, FeO, MgO, CaO, &c.,—a fact brought out very prominently by Professor Dana in the last edition of his *System of Mineralogy*, and in other publications. Hence, if  $Al^2O^3$  sometimes replace SiO<sup>3</sup>, and sometimes replace the bases RO, there is no reason why SiO<sup>3</sup> should not also replace the latter in certain proportions. This granted, our present formulæ may be modified to almost any extent, and sub-groups thus obtained to suit all cases.

From these and other analogous considerations—such as will readily suggest themselves to all who have made the investigation of minerals their study—I think we may fairly admit that crystalline form and atomic composition are not alone sufficient for the foundation of a truly philosophic and satisfactory classification. Important as we may allow these characters to be, they are not all-important. The general aspect of the mineral, as indicating allotropic relations, its conditions of occurrence, and other characters, must also be allowed a certain value in the elaboration of at least our secondary groups.

# ON THE DIVISION OF THE AZOIC ROCKS OF CANADA INTO HURONIAN AND LAURENTIAN.

BY SIR WILLIAM E. LOGAN, F. R. S., DIBECTOR OF THE GEOLOGICAL SURVEY OF CANADA.

Read before the American Association for the advancement of Science, at Montreal, August 13th, 1857.

The Subsilurian Azoic rocks of Canada occupy an area of nearly a quarter of a million of square miles. Independent of their stratification, the parallelism that can be shewn to exist between their lithological character, and that of metamorphic rocks of a later age, leaves no doubt on my mind that they are a series of very ancient sedimentary deposits in an altered condition. The further they are investigated the greater is the evidence that they must be of very great thickness, and the more strongly is the conviction forced upon me, that they are capable of division into stratigraphical groups, the superposition of which will be ultimately demonstrated, while the volume each will be found to possess, and the importance of the economic materials by which some of them are characterized, will render it proper and convenient that they should be recognised by distinct names, and represented by different colors on the geological map.

So early as the year 1845, as will be found by reference to my report on the Ottawa district, presented to the Canadian Government the subsequent year, a division was drawn between that portion which consists of gneiss and its subordinate masses, and that portion consisting of gneiss interstratified with important bands of crystalline limestone. I was then disposed to place the lime-bearing series above the uncalcareous, and although no reason has since been found to contradict this arrangement, nothing has been discovered especially to confirm it; and the complication which subsequent experience has shewn to exist in the folds of the whole,—apparent dips being from frequent overtures of little value,—would induce me to suspend any very positive assertion in respect to their relative superposition, until more extended examination has furnished better evidence.

In the same report is mentioned, among the Azoic rocks, a formation occurring on Lake Temiscamang, and consisting of Siliceous slates and slate conglomerates, overlaid by pale sea-green or slightly greenishwhite sandstone, with quartzose conglomerates. The slate conglomerates are described as holding pebbles, sometimes a foot in diameter, derived from the subjacent gneiss, the boulders displaying red feldspar, translucent quartz, green hornblende, and black mica, arranged in parallel layers, which present directions according with the attitude in which the boulders were accidentally enclosed. From this it is evident that the slate conglomerate was not deposited until the subjacent formation had been converted into gneiss, and very probably greatly disturbed; for while the dip of the gneiss, up to the immediate vicinity of the slate conglomerate, was usually at high angles, that of the latter did not exceed nine degrees, and the sandstone above it was nearly horizontal.

In the report transmitted to the Canadian Government, in 1848, on the north shore of Lake Huron, similar rocks are described as constituting the group which is rendered of such economic importance, from its association with copper lodes. The group consists of the same silicious slates and slate conglomerates, holding pebbles of syenite instead of gneiss; similar sandstones sometimes shewing ripple-mark, some of the sandstones pale sea-green; and similar quartzose conglomerates, in which blood-red jasper pebbles become largely mingled with those of white quartz, and in great mountain masses predominate over them. But the series is here much intersected and interstratified with greenstone trap, which was not observed on Lake Temiscamang.

These rocks were traced along the north shore of Lake Huron, from the vicinity of Sault Ste. Marie, for 120 miles, and Mr. Murray ascertained that their limit on the Lake Shore occurred near Shebahahnahning, where they were succeeded by the underlying gneiss.

The position in which the group was met with, on Lake Temiscamang, is 130 miles to the north-east of Shebahahnahning, and last year Mr. Murray, in exploring the White-Fish river, was enabled to trace the out crop of the group, characterized by its slates, sandstones, conglomerates, greenstones, and copper lodes, for sixty-five miles from Shebahahnahning to the junction of the Maskinongé and Sturgeon rivers tributary to Lake Nipissing. The general bearing of the outcrop is N.E., and an equal additional distance, in the same direction, would strike the exposure on Lake Temiscamang. In the portion which Mr. Murray examined last year, the dip appears to be about N.W., often at a high angle, while that of the subjacent gneiss is more generally S.E.; sometimes at a low angle, and in some places nearly horizontal.

To the eastward of this out-crop, Canada has an area of 200,000 square miles. This has yet been but imperfectly examined, but in so far as investigation has proceeded, no similar series of rocks has been met with in it; and it may safely be asserted that none exists between the basset edge of the Lower Silurian and the group from Shebahahnahning to the Mingan Islands, a distance of more than 1,000 miles, and probably still farther to Labrador.

The group on Lake Huron, we have computed to be about 10,000 feet thick; and from its volume, its distinct lithological character, its clearly marked date posterior to the gneiss, and its economic importance as a copper-bearing formation, it appears to me to require a distinct appellation, and a separate color on the map. Indeed, the investigation of Canadian Geology could not be conveniently carried on without it. We have, in consequence, given to the series the title of Huronian.

VL. II.---E\*

A distinctive name being given to this portion of the Azoic rocks, renders it necessary to apply one to the remaining portion. The only local one that would be appropriate in Canada is that derived from the Laurentide range of mountains, which are composed of it, from Lake Huron to Labrador. We have therefore designated it as the Laurentian series.

These local names are, of course, only provisional, devised for the purpose of avoiding periphrastic or descriptive titles, the use of which had been found inconvenient, and they can be changed when more important developments, proved to be the equivalents of the series, are met with elsewhere.

## REVIEWS.

Essay on the Insects and Diseases injurious to the Wheat Crops. By H. Y. Hind, Esq., M.A., Professor of Chemistry at Trinity College, Toronto; to which was awarded by the Bureau of Agriculture and Statistics, the first prize. Toronto: Printed by John Lovell, 1857.

This essay,—the product of a competition for prizes recently offered by the Canadian Minister of Agriculture, ---is quite as good as could have been expected, considering the circumstances under which it was produced. It is a compilation, and it could not well have been anything else : but it shows knowledge of the subject, industry, and judgment. If our farmers and country gentlemen take the trouble to examine it, they will doubtless derive much benefit from it. Some of them may, perhaps, say that it is too scientific for them and may fancy it better suited to the incipient entomologist than to the practical man; but the truth is, if any better means than we possess (which are but very imperfect) for controlling the ravages of insect pests are to be discovered, it must be through a knowledge of their nature and mode of life. Practical men have need of a certain amount of scientific knowledge, and Professor Hind gives the assistance many of them require in a clear, simple, intelligible style, without much superfluous matter. The practical suggestions are generally sound and useful, and as the reasons for them are explained, every one is enabled to form his own judgment.

The essay is not of mere temporary interest; it is a useful digest on a highly important subject, of what is to be found in various volumes, and in detached essays and observations scattered through periodicals; such as Harris' Insects injurious to vegetation, Fitch's

Essay, Kirby and Spence's Manual, &c. We are not aware that the author has availed himself of the valuable original work of Kollar, on injurious insects, which is in reality the chief source from whence the writers on this subject have derived much of their more valuable information.

Whilst the author has entitled himself to much credit for his diligence and research, we think the Minister of Agriculture may be satisfied with the working of his scheme, and may congratulate himself on having obtained for a very moderate copyright what cannot but be beneficial to the country. But where are the other prize essays ? We expected to have seen all published in one volume; or at least a volume for Western Canada containing the two English essays, and one for Eastern Canada, containing the French prize essay, with a translation of Mr. Hind's. It would even, perhaps, not be lost labour to cull something for public use from the other essays, some of which the judges have named as containing valuable matter; and which even where they have the least pretension to literary merit, knowledge, or research, would doubtless, in some instances, convey a fact or opinion, which, communicated by a practical man and from patriotic motives, is not unworthy of being recorded. There may be obstacles to what we suggest, in the Bureau not claiming a right to use essays to which no prize has been awarded, in the cost of printing, and in a reasonable apprehen. sion that increase in the quantity of matter diminishes the probability of its being made use of. But it is a pity not to secure all the benefit attainable from the labours of those who sent in their observations. some of them probably without expectation of reward, but with a desire to do what they could for the public service. It is hardly necessary to quote from Mr. Hind's essay, which will be in the hands of all who are interested in its subject. We congratulate him on the honorable distinction he has attained, and recognize with pleasure the merit of his work.

W. H.

Crania Britannica.—Delineations and descriptions of the skulls of the early inhabitants of the British Islands, together with notices of their other remains. By Joseph Barnard Davis, M.R.C.S.E., and John Thurnam, M.D. Decades I and II. London, Taylor and Francis.

In the introduction to this national work, the joint product of the zealous labours of Mr. J. Barnard Davis and Dr. Thurnam, Mr.

#### REVIEWS-CRANIA BRITANNICA.

Davis plainly sets forth their aim, as a further effort in the same direction as "the two first permanent and beautiful superstructures" of the science of comparative cranioscopy, reared by Morton on the earlier toundations of Blumenbach. In all directions the enthusiastic students of British History are aiming to extend our vision further and more clearly into the past. Dr. Todd, Algernon Herbert, Graves, and a host of other zealous Celtic scholars, are restoring to us the most ancient native Literature of the British Isles. Kemble and Thorpe, following in the wake of Sharon Turner, with greater advantages and profounder scholarship, have thrown fresh light on the Anglo-Saxon era; Palgrave continues those labors which promise to complete the links requisite to unite in complete coherence Norman and Saxon England ; and Latham, Petrie, Wright, Ackerman, Roach Smith, and other Archæologists and Philologists, extend their researches in various directions, and add new and diverse contributions to the same end. It is well, therefore, that such zealous co-adjutors as the authors of the Crania Britannica should be welcomed, in undertaking to add to all these one more resurrection from the ancient past, and to treat with adequate minuteness and accuracy of detail, another department of the theme which our great English Ethnologist, Pritchard, dealt with in so masterly a style.

The design aimed at in this new contribution to British Ethnology is, " to apply the study of the minuter diversities in the form of the skull to the discrimination and elucidation of the various ancient races who have dwelt in the British Islands, the forerunners, at least, if not the progenitors, of a people who may be safely assumed to occupy a place in future history, inferior to none who have preceded them. The investigation of the facts connected with these races is involved in obscurity from their remoteness in time; the want of information to be derived from the scanty notices of ancient writers, whether the consequence of imperfect knowledge, or inaccurate observation, or their use of ill-understood general terms; and especially from the fanciful speculations of learned theorists." To supply some of the desiderata thus deplored, an examination of the personal remains of the ancient people is accordingly resorted to. Their memorials of ancient arts, domestic habits, military skill, and sepulchral rites. have each and all been made to contribute their quota. Now, it is proposed to ascertain the ancient lineaments and physical characteristics of the people themselves, by means of the still enduring osseous remains of those who "swayed the rod of empire," while vet the cradle-land of Anglo-Saxondom was the seat of Celtic ..

and the arena of the Briton's untold history; or when the Saxon colonist was entering amid the Druid oak-glades of England, a stranger, like his hardy descendant who pioneers the way amid the primeval forests of our far-west. Morton, in his Crania Americana, dealt with the ethnic craniology of a very wide and nearly virgin area. From the northern Arctic circle, to where the Terra del Fuego reaches towards Antarctic snows, the American Ethnologist sought to gather his materials, and from the data thus accumulated, conclusions applicable to the two continents of the new world have been deduced. Compared with such a wide field of investigation, the little island-home of the Saxons may well seem narrow ground for exploration. But to the Ethnologist it is not so. There, amid the rudest traces of primeval arts, he seeks, and probably not in vain, for the remains of primitive European Allophyliæ. There it is not improbable that both Phœnician and early Greek navigators have left behind them evidences of their presence, such as he alone can discriminate. There unquestionably was the home of the antechristian Celt, and of the Picts, the Scots, the Belgæ, and other races of disputed origin. There, too, the Roman not only abode for upwards of three centuries, and left enduring memorials of his presence, but his sculptured tablets still attest the introduction by him of legionary colonists, not only from Gaul, Germany, Spain, and Italy, but from Asia Minor and Africa. Colonists from almost every people who had been subdued by the Roman arms were planted among the subject Britons, and these not in indiscriminate collocation, but each nationality with its own station assigned to it, where votive inscriptions and sepulchral tablets still guide the curious explorer to classify the remains he exhumes. There, too, in that same historic soil, lie the remains of the old Scandinavian Viking, Dane and Norseman, buried with the pomp of Pagan sepulture, that still tells of his northern birth-land.

As an example of the accuracy of the data thus open to investigation: amid the beautifully executed plates of life-sized crania of ancient Britons, Caledonians and Saxons, appear also more than one of the Roman conquerors. One of these was procured from a sculptured stone sarcophagus, on the outskirts of the ancient Roman Eburacum, or English York, around which lay numerous urns, pateræ, a terra-cotta lamp, and other remains of the foreign arts of the Roman Colonist. The partially mutilated Sarcophagus, belonging to the second, or at latest, the third century of our era, and is an invaluable adjunct, alike for the purposes of the Antiquary and the Ethnologist, from its bearing an inscription, which reads :---

MEI . . . AL. THEODOBI ANI . . OMENT. VIXIT. ANN XXXIV. M. VI. EMI. THEO DO :: A. MATER. E. C

Imperfect as the memorial now reaches us, there is no doubt of its general tenor. It is the dedication by the Roman Matron Theodora, to the memory of her son, Theodorianus, who died at the age of thirty-four, in that remote outpost of the empire. far from Nomentum. his Latian or Sabine home. The skull of Theodorianus is a fine example of the old Roman cranium. Dr. Thurnam remarks of it :--"It is unusually capacious, and its dimensions are much above the average in almost every direction." The deductions from this single skull well illustrate how far such materials may contribute to the recovery of minute and accurate knowledge in the hands of a cautious and experienced observer. The fine aquiline profile is still discernible, slightly marred by a partial prognathic character in the jaws and position of the teeth. The uneroded crowns of the latter suffice to show the nature of the diet, and the civilized habits of the old Roman, in contrast to those of the native Britons of his age. Still further the condition of the sutures, and of the internal surface of the skull, suggest the habits of the soldier, who had not passed through the ordeal of war without sharing freely in its dangers.

"There is conclusive evidence in this noble cranium of Theodorianus," says Mr. Davis, "—the like of which we by no means anticipate meeting with in the further course of our labours,—that he was a fine Roman, of tall stature, over whose premature decease a tender mother might naturally grieve with a deep sorrow. His native country was near the imperial city itself, his family, without doubt, of consequence, and his residence in Britain possibly connected with the command of the legion which garrisoned Eburacum for so many years."

In dealing with the sepulchres of the old Briton or Saxon, the Ethnologist cannot, as with the Roman, quote the inscription which records the name and age, the birth place, and the race of the owner. But other and scarcely less intelligent records supply its place. In the *Crania Britannica* there are accordingly introduced, along with the beautifully executed cranial illustrations, other plates, besides wood cuts, which show unmistakeably the very diverse character of the sepulchral disclosures which establish the evidence of

ownership in the old burial mounds and cists of the British Isles. Here are engraved the primitive cinerary urns and domestic pottery from the ancient British Barrows of Staffordshire and Derbyshire. and the rude stone cist of Juniper Green, near Edinburgh. The flint implement of Ballidon Moor Barrow, tells of the rudest barbarism of Britain's primeval night; while at the same time such sepulchral architecture as the Gloucestershire chambered and galleried tumulus of Uley, the Derbyshire cist and megalithic mound of Parsley Hay Low, or the cist and superincumbent urn-chamber of Ballidon Moor, reveal the mode of thought of an era, analogous in its constructive ideas to that which gave birth to the pyramids and catacombs of the Nile valley. Another era succeeded, of the arts of which, the bronze dagger of End Low Barrow, Derbyshire, and the horse furniture, glass beads, and personal ornaments of the Yorkshire Barrows, furnish striking illustration; and then we come to the Iron umbos and spearheads, and the ponderous sword, of the Saxon Graves of Salisbury and Gloucester, the situla and cinerary urns of Linton Heath, Cambridgeshire, and with these the curiously ornamented glass vase, the fibulæ, and the toilet implements of Saxon times. Between the first and last of these, the era of Theodorianus intervenes, with the sculptured and inscribed Sarcophagi, the classic pottery and other intruded foreign arts of Roman Yorkshire; and, later than all, the Dane and Norseman tell, by Runic inscriptions and sepulchral hoards of the implements and the weapons of Northern Europe, how another, and yet another wave of colonization, mingled the diverse races of Europe with the elder colonists of the British Tsles.

Such is the rich field of Ethnological research which Dr. Thurnam and Mr. Davis have undertaken to explore and to illustrate, with the added feature of accurate and critical descriptions and drawings of the osteological remains. The work is to be published in six "Decades," of which two only have appeared, embracing as yet incompleted chapters, and partially apportioned illustrations to some of the completed descriptions. Some of the most important questions that have recently attracted the attention of British Ethnologists and Archæologists, are expressly reserved for discussion at the close, and even of those which may be assumed to be completed, such as the interesting and suggestive one from the pen of Mr. Davis, on "Distortions of the Skull," it is to be anticipated that further illustrations may incidentally occur during the progress of the work. It would obviously, therefore, be premature to anticipate the final de-

#### CHEMISTRY.

ductions of the authors, or to discuss the comprehensive questions which the work illustrates, from imperfect and unclassified materials. Meanwhile we may record our conviction, that for beauty of typography, and artistic skill and minute accuracy of illustration, we can scarcely conceive the work surpassed. When completed it will form a mine of information to be worked by many a succeeding laborer, and must be considered as an indispensable addition to every public and scientific library.

## SCIENTIFIC AND LITERARY NOTES.

## CHEMISTRY.

#### FLUORINE.

Nicklès is of opinion that the usual test for fluorine is not  $s \not = reliable$  as has been supposed. Sulphuric acid, however carefully purified, often contains traces of hydrofluoric acid, and also from the fact that the vapours of any acid, or even of water at a rather elevated temperature, are capable of acting upon glass so as to produce an engraving similar to that obtained by hydrofluoric acid, additional grounds for doubt exist. He recommends the substitution of plates of rock crystal for those of glass, that substance being acted on only by hydrofluoric acid.

## ALUMINA.

Gaudin has obtained hard, brilliant and clear crystals of alumina by introducing into a crucible, luted with lamp-black, equal parts of common alum and bisulphate of potassa, previously calcined and reduced to powder. The crucible is submitted to the violent heat of a blast furnace for a quarter of an hour. On breaking the crucible we find, in the hollow of the luting, a concretion bristling with brilliant points. The alumina is separated by dilute nitromuriatic acid.

#### TANTALUM.

Rose has obtained a nituret of tantalum, and has described the processes for obtaining tantalic acid, perfectly pure, by fusion with the bisulphate of potassa or ammonia. The acid dissolves in the latter salt, forming a clear syrup, which remains clear for years; the solution takes place at a temperature below a dull red heat, and may be effected in a glass flask. Tantalic acid, obtained by the decomposition of the perchloride, or by the action of sulphurous acid on a solution of the tantalate of soda, differs from that obtained by fusion, inasmuch as it exhibits incandescence when heated, which the other does not. From this and other circumstances Rose concludes that there are two modifications of tantalic acid, the one convertible into the other by heat. He has also examined the various salts which it forms with potassa.

#### TANNIN.

By acting upon some organic compounds with boiling alkaline solutions, in an atmosphere of hydrogen, Rochleder has succeeded in decomposing several, and producing grape sugar. Tannin, when thus treated, readily gives oxalic acid, and a yellowish amorphous substance, like gum arabic, having the same composition as cane sugar but none of its reducing power. No trace of sugar is formed during this reaction.

#### STRYCHNINE.

Prollius proposes a method for separating strychnine, which promises to be of considerable value in toxicological investigations. The substance is digested with alcohol and a little tartaric acid, gently evaporated to a small bulk, and filtered to separate the fat. (If evaporated to dryness the fat might be separated by ether, which does not dissolve salts of the alkaloids.) To the filtrate ammonia is added, then a small quantity of chloroform, and the whole strongly agitated. The chloroform, which settles to the bottom, is drawn off and washed, mixed with three times its bulk of alcohol, and allowed to evaporate. Fine crystals of strychnine are thus obtained in a state of absolute purity.

### MATHEMATICS AND NATURAL PHILOSOPHY.

THE RELATIONS OF GOLD TO LIGHT.

At a meeting of the Royal Institution, in June last, Professor Faraday read a communication on the relation of gold to light. In this he furnished additional views and observations of great interest, in continuation of a former paper on the same subject, read by him last year, and printed in the Proceedings of the Royal Institution (Vol. II. p. 310.) The general relations of gold leaf to light are described in the former communication. The following is a summary of the additional remarks which complete the report of Professor Faraday's observations on the subject up to this time :- Since the printing of the former paper pure gold leaf has been obtained, through the kindness of Mr. Smirke, and the former observations verified. This was the more important in regard to the effect of heat in taking away the green colour of the transmitted light, and destroying to a large extent the power of reflection. The temperature of builing oil, if continued long enough, is sufficient for this effect; but a higher temperature (far short of fusion) produces it more rapidly. Whether it is the result of a mere breaking up by retraction of a corrugated film, or an allotropic change, is uncertain. Pressure restores the green colour, but it also has the like effect upon films obtained by other processes than beating. Corresponding results are produced with other metals. As before stated, films of gold may be obtained on a weak solution of the metal, by bringing an atmosphere containing vapours of phosphorous into contact with it. They are produced also when small particles of phosphorous are placed floating on such a solution; and then, as a film differing in thickness is formed, the concentric rings due to Newton's thin plates are produced. These films transmit light of various colours. When heated they become amethystine or ruby, and then when pressed become green, just as heated gold leaf. This effect of pressure is characteristic of metallic gold, whether it is in leaf, or film, or dust. Gold wire, separated into very fine particles by the electric deflagration, produces a deposit on glass, which, being examined, either chemically or physically, proves to be pure metallic gold. This deposit transmits various coloured rays; some parts are grey, others green, or amethystine, or even a bright ruby. In order to remove any possibility of a compound of gold, as an oxide, being present, the deflagrations were made upon topaz, mica, and rock crystal, as well as glass, and also in atmospheres of carbonic acid and of hydrogen. Still the results were the same, and ruby gold appeared in one case as much as in another. Being heated, all parts of the deposit became of an amethystine or ruby colour; and by pressure these parts could be changed so as to transmit the green ray. The production of *fluids*, consisting of very finely divided particles of gold diffused through water, was spoken of before. These fluids may be of various colours, by transmitted light, from ruby to blue; the effects being produced only by diffused particles of metallic gold. If a drop of solution of phosphorous in bisulphide of carbon be put into a bottle containing a quart or more of very weak solution of gold, and the whole be agitated, the change is brought about sooner than by the process formerly described ; or if a solution of phosphorous in ether be employed, very quickly indeed; so that a few hours' standing completes the action. All the preparations have the same qualities as those before described. The differently coloured fluids may have the coloured particles partially removed by filtration; and so long as the particles are kept by the filter from aggregation, they preserve their ruby or other colour unchanged, even though salt be present. If fine isinglass be soaked in water, then warmed to melt it, and one of these rich fluids be added, with agitation, a ruby jelly fluid will be obtained, which, when sufficiently concentrated and cold, supplies a tremulous jelly; and this, when dried, yields a hard ruby gelatine, which being soaked in water becomes tremulous again, and by heat and more water yields a ruby fluid. The dry hard ruby jelly is perfectly analagous to the well known ruby glass, though often finer in colour, and both owe the colour to particles of metallic gold. Animal membranes may in like manner have ruby particles diffused through them, and then are perfectly analogous in their action on light to the gold ruby glass, and from the same cause. When a leaf of beaten gold is held obliquely across a ray of common light, it *polarizes* a portion of it, and the light transmitted is polarized in the same direction as that transmitted by a bundle of thin plates of glass; the effect is produced by the heated leaf as well as by the green leaf, and does not appear to be due to any condition brought on by the heating, or to internal structure. When a polarized ray is employed, and the inclined leaf held across it, the ray is affected, and a part passes the analyzer, provided the gold film is inclined in a plane forming an angle of 45° with the plane of polarization. Like effects are produced by the films of gold produced from solution and phosphorous, and also by the deposited dust of gold due to the electric discharge. The same effects are produced by the other deflagrated metals so long as the dusty films are in the metallic state. As these finer preparations could be held in place only on glass or some such substance, and as glass itself had an effect, it was necessary to find a medium in which the power of the glass was nothing; and this was obtained in the bisulphide of carbon. Here the effect of gold upon a ray of light which was unaffected by the glass supporting it, was rendered manifest, not only to a single observer, but also to a large audience. The object of these investigations was to ascertain the varied powers of a substance acting upon light, when its particles were extremely divided, to the exclusion of every other change of constitution. It was hoped that some of the very important differences in the action upon the rays might in

this way be referred to the relation in size or in number of the vibrations of the light and the particles of the body, and also to the distance of the latter from each other, and as many of the effects are novel in this point of view, it may be anticipated that they will prove of service to the physical philosopher.

## THE SUPPOSED DECENNIAL INEQUALITY IN THE LUNAR-DIURNAL MAGNETIC VARIATION.

In 1854 General Sabine stated to the British Association that he had at that time found no trace, in the magnetic variations depending on the moon, of the ten-years period which is so distinctly marked in those depending on the sun, and in 1856, after an elaborate discussion of the Toronto observations, he stated this conclusion to be decisively confirmed. M. Kreil having, however, indicated an opinion that the observations at Milan and Prague rather favored the supposition that the same decennial period which exists in the solar variation affects also the lunar magnetic influence, General Sabine, with the unwearying zeal which distinguishes him, has submitted to analysis the eight years observations at Hobarton, and finds therein confirmation of the conclusions he had arrived at from the Toronto observations, namely, that no such decennial period as Mr. Kreil supposed is to be traced in the magnetic influence of the moon, while such a period is indubitably shewn in that of the sun, whether examined by means of the "disturbances," or of the "mean" solar variation. With regard to the former General Sabine remarks that, "when the disturbances, occurring at Hobarton during eight years, are broken into four distinct and equal portions, each of two years duration, each such portion manifests the same periodical law of diurnal variation, almost identical in the principal features of direction and turning hours, and differing only in the magnitude of the variation in different years, in which difference it conforms strictly to the decennial period, as indicated elsewhere, having a minimum in 1843-44, and a maximum five years later. This law may be accounted a general one, since it has been found to prevail at stations so widely distant from each other as Toronto, St. Helena, and Hobarton." The same result follows when the mean diurnal solar variation, the larger disturbances being excluded, is examined, both for the eight years 1841-8, when the observations were made hourly, and also when the six succeeding years are included, during which twohourly observations were taken. By treating in the same way the lunar-diurnal variations, General Sabine shows that the differences in these "show no conformity to the inequality manifested in those of the solar-diurnal variations." With this weight of evidence, we may fairly conclude that the ten years' period has no existence for the moon, and thank General Sabine for the settlement of this vexed question.

## ON THE COMPOSITION OF COLOURS.

Professor Challis, in the Phil. Mag., November, 1856, has attempted to give an explanation of this difficult matter, on the principles of the undulatory theory. Taking for his guide the analogy of sound, and a hint thrown out by Sir J. Herschel in his well-known treatise, Professor Challis proceeds to compound two simple undulations of different wave-lengths. As a musical note is produced by a regular succession of similar vibrations, while a mere noise is produced by irregular impulses, so he conceives a simple colour to consist of vibrations, whose type composes only one wave length and amplitude, while a mixed colour, of whiteness, is produced by the coëxistence of different types; melody thus corresponding to pure colour, harmony to mixed colour, and unmusical noise to white

light. By throwing the compounded velocity of two colours (taking the usual cycloidal type) into a peculiar analytical form, he shows that the resulting vibration will consist partly of a colour whose wave-length is a harmonic mean between those of the original, and partly of irregularities, which may cause the sensation of whiteness, and dilute the colour, and may sometimes be powerful enough to overcome the sensation of colour altogether. This, however, requires that the maximum velocities in each vibration shall not be very different from each other, and Professor Challis ingeniously employs this to account for the fact that the mixing of coloured substances produces different results from the mixing of the prismatic colours which to all appearance are identical with the former. The method gives a good explanation of complementary colours, and of several other well-known facts in colour compounds, as given by Newton, Helmholtz, Maxwell, and others. It also leads to the abandonment of the doctrine (always looked on with suspicion) of three primitive colours. There is one point Professor Challis does not notice, which is this: in the composition of two musical notes, whether, by the superposition of vibrations on the vibrating body (as in a string, giving out two notes at the same time), or by their union on entering the ear, each note is still heard separately, and the sensation of harmony is altogether different from the perception of its components; in colour, however, the union of the two may destroy this perception of the components, and give rise to a single sensation only. Now, if we take the same precise analytical forms of vibration in the two cases, it does not appear manifest how this distinction may be made visible in the analytical result. The whole subject is, however, a very difficult one, and, whether altogether sound or not, this idea of Professor Challis is well worth carrying out.

#### PROFESSOR W. THOMSON'S BAKERIAN LECTURE (R. S., FEB. 28, 1856.)

This lecture communicates some most valuable discoveries and experiments made by the author in electro-thermotics. (1.) An electric current in an unequally heated conductor, if its nominal direction be from hot to cold through the metal, causes a cooling effect in iron and a heating effect in copper. Brass has the same property as copper, and platinum as iron, with respect to this electric conversion of heat. (2.) In thermo-electric inversion between metals, a mode of experimenting is described by which inversions, when they exist, may readily be detected, and the temperature of neutrality determined with precision. Various substances have in this way been subjected to trial by the author. (3.) The effects of mechanical strain, and of magnetisation, on the thermo-electric qualities of metal, are investigated. In a mass of iron under longitudinal stress, the thermo-electric quality across lines of traction differs from that along lines of traction as bars of bismuth differ from bars of antimony. Unstrained iron has intermediate thermo-electric quality between those of the two critical directions under distorting stress. The effect of permanent lateral compression is the same as that of permanent longitudinal extension, or of hardening by wire-drawing, upon the thermo-electric quality of a wire placed lengthwise in an electric circuit in iron, being a deviation from the [un?] constrained metal towards bismuth, and in the other metals (copper, tiu, brass, platinum, cadmium and lead [?]), a deviation towards antimony; also that in copper and iron, it is the reverse of the effect experienced by the same metal while under the stress that caused the strain. Generally, it is inferred, that in iron hardened by compression in one direction,

the thermo-electric qualities in this direction differ from those in lines perpendicular to it as antimony differs from bismuth; that the reverse statement applies to iron hardened by traction in one direction; and that in each case the thermoelectric quality of soft iron is intermediate to the two differing states.

Again, in soft iron under magnetic force, and in that permanently magnetised after the removal of the magnetising force, directions along the lines of magnetisation deviate thermo-electrically towards antimony, while those perpendicularly across the lines of magnetisation deviate towards bismuth, from the unmagnetised metal. Thus if a riband of iron, magnetised at an angle of 45° to its length, be heated along one edge while the other is kept cool, when the two ends, kept at the same temperature are put in communication with the electrodes of a galvanometer, a powerful current is indicated, in such a direction that, if pursued along a rectangular zigzag from edge to edge through the band, the course is always from across to along the lines of magnetisation through the hot edge, and from along to across the same lines through the cold edge. (4.) Various experiments were made to detect the effects of certain influences on the electric conductivities of metals. For instance, longitudinal magnetisation diminishes the conducting quality of iron wire, and its electric conductivity is greater across than along lines of magnetisation; also, by magnetisation across the lines of electric current, iron gains in conducting power, whence it is inferred that there is a certain direction, oblique to the lines of magnetisation, along which the conductivity of magnetised iron would remain the same on a cessation of the magnetising force.

#### ON THE TEMPERATURE AT TORONTO.

In the Phil. Mag., Nov., 1856, Mr. S. M. Drach points out that General Sabine's formula (Phil. Trans., 1852) can be put approximately into the simple form---

44°.23—21°.81 sin a—1°.06 cos 2a—0°.80 cos  $3a_{+}$ 0°.22 cos  $4a_{-}$ 0°.88 sin 5a where a is the angle reckoned at 30° a month from October 24th, which is the epoch of mean annual temperature. Hence he suggests that the meteorological year should be taken from October to September inclusive.

#### A NEW SPHYGMOSCOPE .- BY DR. S. SCOTT ALISON, (PROC. L.S.)

This instrument, designed for the purpose of indicating the movements of the heart and blood-vessels, consists of 'a small chamber containing spirits of wine or other liquid, provided with a thin india-rubber wall where it is to be applied to the chest. This chamber communicates with a bent graduated tube which rises to some height above the level of the chamber; liquid is supplied to the instrument till it spreads in the tube a little above the level of the chamber. The pressure of this liquid, acting on the elastic wall, causes it to protrude, and the protruding part is very sensible to external impulse, yielding to the slightest touch, and, being pushed inwards or returning outwards, causes a rise or fall of the liquid in the tube, the amount and duration of which can be estimated with much delicacy. By means of this instrument, Dr. Alison has detected two great laws not hitherto known, namely, 'that the beat of the heart *alternates* with the pulse of the wrist,' and, 'that the pulse of arteries beyond the chest takes place in all parts at the same instant, and without any appreciable interval.'"

#### PHOTOGRAPHY.

The attention of Photographers has been mainly directed of late to the perfecting of some dry process by which the necessity of immediately using the wet

collodion film may be obviated. Many modifications of Shadbolt's original honeyprocess have been proposed, and the use of various substances, such as glycerine metagelatine, golden-syrup, oxymel, has been recommended, all adopting for their basis the principle of washing off the free nitrate of silver after the plate has been excited, and then covering it with the preservative syrup which keeps it moist and prevents the small excess of free nitrate left on the collodio-iodide from drying and crystallising. Another plan, claimed by several originators, is remarkable, consisting in leaving the excited plates in distilled water, when, if protected from the light, they will retain their sensitiveness for weeks unimpaired. The most promising however seems to be Taupenot's Albumen process (described in Can. Journ., Vol. I., N.S., pp. 195) of which the following is the latest simplification, as practised by Mr. H. P. Robinson. The Nitrate-Bath consists of: Nitrate of Silver, 35 grs., Glacial Acetic Acid, 1 min., Distilled Water, 1 oz. Having coated the plate with collodion, and excited as usual, let it be immersed for about one minute in distilled water, then washed for two or three minutes under a tap, allowed to drip for a minute, and then have poured over it some iodised albumen which need only remain for a few seconds on it. This iodised albumen is made as follows: Albumen, 1 oz.; Distilled Water, 2 drachms; Ammonia, 8 minims; Iodide of Ammonia, 5 grs.; Bromide of Ammonia, 1 gr.; dissolve the iodide and bromide in the water, and then add the ammonia to the albumen, beat the whole into a froth, and, when again liquified, strain through calico. The plates may now be put away to dry; they are perfectly insensitive to light, and will keep for any length of time. When wanted for use, dip them again into the nitrate-bath for one minute, and wash precisely as before. They are now ready for the camera, and may be kept (in darkness of course) for weeks without losing sensitiveness. Develope with pyro-gallic acid, adding free nitrate, if necessary, (this is a long process), and fix with hyposulphite of soda.

Mr. Hardwich has brought out another edition of his excellent treatise on Photographic chemistry: he now recommends the use of fused nitrate of silver instead of the crystallised. Mr. Scott Archer, the inventor of the Collodion process has died, leaving a widow and family in distressed circumstances. A committee of the Photographic Society has been formed to raise a subscription for them and to urge their claims on government for pecuniary aid. Mr. Crookes and Mr. Grubb have succeeded in procuring photographic images of the moon-the former with the Liverpool Equatorial obtaining good negatives in four seconds. No practical benefit seems likely to result from this mode of operation, as the minute image thus formed loses its distinctness on being magnified. Is Bromine of any use in Photography? It seems conceded that in the paper-processes Bromine is useful in gaining intensity; but in collodion there does not appear to be the same result. For some time it was imagined that the Bromide was peculiarly sensitive to the green rays of the spectrum, and was on this account advantageously employed when vegetation and foliage were to be photographed; but Mr. Crookes has shown that the only part of the spectrum where it enjoys any advantage over the Iodide is the unimportant and narrow strip between Fraunhofer's b and G, so that its fancied superiority vanishes compared with the injury it inflicts on the film. Mr. Shadbolt has confirmed by a remarkable experiment the inference of M. Claudet, that the yellow rays not only destroy the actinic effect of the blue, but actually reverse it. Mr. Shadbolt says: "I coated and excited a glass plate in the usual way, and exposed it to the light. I then took a piece of stained

yellow glass and covered with it one half of this plate. I then exposed the whole to the direct rays of the sun for ten minutes, and afterwards placed the same plate in the camera in order to attempt to take a picture upon it. In developing, the part I had covered with yellow glass after previously exposing the whole to the light, produced a picture, (though not a very good one), and the part left uncovered, produced, as might have been expected, a perfect mass of blackness; hence I conclude that the yellow glass undid the work that had previously been done by the ordinary light."

Photographers seem now to be pretty generally convinced that positive paper prints, if toned by hyposulphite of soda, will fade when exposed to moisture. Mr. Shadbolt publishes a process in which sulphide of silver (a permanent compound) is substituted for the ordinary sulphuret. The paper is salted on a bath of gelatine, 1 gr.; Chloride of Ammonium, 10 grs; Water, 1 oz. After exposure, it is washed with water, then with liq. amm. fort. diluted with four or five times its bulk of water; again washed with plain water, and then toned with a solution of hydrosulphite of ammonia; a final washing and drying completes the picture. The tone is said to be an agreeable brownish black, which acquires a yellowish tinge by time.

#### THE GREENWICH OBSERVATORY.

In the report of the Astronomer Royal to the Board of Visitors, the following curious fact is mentioned: "There is a well-marked annual periodical change in the position of the Transit Circle, the southerly movement of the eastern pivot having its minimum value in September, and its maximum in March, the extreme range being about 14 seconds; and there is a similar change, but of smaller amount, in the position of the Collimator. I cannot conjecture any cause for these changes, except in the motion of the ground. There is a very frequent change of still smaller amount in the Azimuth of the Transit Circle, accompanied by a nearly equal change in the apparent Azimuth of the Collimator, so that from day to day the Transit Circle and Collimator preserve their relative position unaltered; these I conceive to be the effects of accident in observation of the circumpolar stars, arising either from fault of the observer, or from irregularities either in the level or in the collimation ; at the same time, viewing the great accuracy of the observations of circumpolar stars, and the extreme simplicity of the pivotsupports and of the instrument frame, I cannot conjecture how such irregularities can arise." During the past winter, Mr. Airy received intimation from Prof. Hansteen that the dip, as determined at Greenwich, appeared to have become greater than was consistent with the changes of dip going on in the North of Europe. A similar discordance was found to exist between Greenwich and Kew. This led Mr. Airy to examine the observatory instrument, and it was found so imperfect in its mechanical construction, that when the needle was lifted up from its agate bearings, its upper point almost always struck the brass circle. These defects have been amended, and the apparent dip is diminished by nearly the quantity which Prof. Hansteen conjectured. Mr. Airy regrets that this irregularity unfortunately causes the dip-observations at Greenwich for several years past to possess very little value.

## COLONIAL MAGNETIC OBSERVATORIES .- BY MAJOR GEN. SABINE. (PROC. R. S.)

The magnetic investigations designed to be carried into execution by the Colonial Observatories recommended by the Royal Society, embraced a much wider

scope than had been contemplated by any previous institutions, or than had been provided for by the arrangements or instrumental means of any then existing establishment, whether national or private. Not, as previously, limited to observations of a single element (the declination)-or combining at the most one only of the components of the magnetic force,—the instructions of the Royal Society. and the instrumental means prepared under its direction, provided for the examination, in every branch of detail, of each of the three elements which, taken in combination, represent, not partially, but completely, the whole of the magnetic affections experienced at the surface of the globe, classed under the several heads of absolute values, secular changes, and variations either periodical or occasional, -and proceeding from causes either internal or external. To meet the requirements of inductive reasoning, it was needful the results to be obtained should comprehend all particulars under these several heads, attainable by an experimental inquiry of limited duration. That no uncertainty might exist as to the objects to which, in so novel an undertaking, attention was to be directed, the Report of the Committee of Physics, approved and adopted by the President and Council of the Royal Society, stated in a very few sentences, remarkable alike for their comprehensiveness and conciseness, the desiderata of magnetical science. It may be convenient to reproduce these, when desiring to show the degree in which the Observatories have fulfilled their contemplated purposes .-- "The observations will naturally refer themselves to two chief branches, into which the science of terrestrial magnetism in its present state may be divided. The first comprehends the actual distribution of the magnetic influence over the globe, at the present epoch, in its mean or average state, when the effects of temporary fluctuations are either neglected or eliminated by extending the observations over sufficient time to neutralise their effects. The other comprises the history of all that is not permanent in the phenomena, whether it appear in the form of momentary, daily, monthly, or annual change and restoration; or in progressive changes not compensated by counter-changes, but going on continually accumulating in one direction, so as in the course of many years to alter the mean amount of the quantities observed."

With reference to the first of these two branches, viz., the actual distribution of the magnetic influence over the globe at the present epoch, the Report goes on to state :—" The three elements, viz. the horizontal direction, the dip, and the intensity of the magnetic force, require to be precisely ascertained, before the magnetic state of any given station on the globe can be said to be fully determined .....and as all these elements are at each point now ascertained to be in a constant state of fluctuation, and affected by transient and irregular changes, the investigation of the laws, extent, and mutual relations of these changes is now become essential to the successful prosecution of magnetic discovery."

With reference to the second branch, viz., the secular and periodical variations, it is observed that—"The progressive and periodical being mixed up with the transitory changes, it is impossible to separate them so as to obtain a correct knowledge and analysis of the former, without taking express account of and eliminating the latter;" and with reference to the secular changes in particular, it is remarked—"These cannot be concluded from comparatively short series of observations without giving to those observations extreme nicety, so as to determine with perfect precision the mean state of the elements at the two extremes of the

period embraced; which, as already observed, presupposes a knowledge of the casual deviations."

It is clear from these extracts that in the discussion of the observations, the first point, in the order of time, ought necessarily to be an investigation into "the laws, extent, and mutual relations of the *transient* and," (as they were called at the time the Report was written,) *"irregular* changes," as a preliminary step to the elimination of their influence on the observations, from which a correct knowledge and analysis of the progressive and periodical changes were to be obtained. It will be proper to show therefore, in the first place, what the Observatories have accomplished in regard to the so-called casual or transitory variations.

Casual Variations.-All that was known regarding these phenomena at the period when the Report of the Committee of Physics was written, was, that there occurred occasionally, and, as it was supposed, irregularly, disturbances in the horizontal direction of the needle, which were known to prevail, with an accord which it was impossible to ascribe to accident, simultaneously over considerable spaces of the earth's surface, and were believed to be in some unknown manner connected, either as cause or effect, with the appearances of the aurora borealis. The chief feature by which the presence of a disturbance of this class could be recognised at any instant of observation,---or by which its existence might be subsequently inferred independently of concert or comparison with other Observatories, -appeared to be, the deflection of the needle from its usual or normal position to an amount much exceeding what might reasonably be attributed to irregularities in the ordinary periodical fluctuations. The observations which had been made on the disturbances anterior to the institution of the Colonial Observatories had been chiefly confined to the declination. A few of the German Observatories had recently begun to note the disturbances of the horizontal force; but as yet no conclusions whatsoever had been obtained as to their laws : in the words of the Committee's Report, the disturbances "apparently observe no law." By the instructions cited above, the field of research was enlarged, being made to comprehend the disturbance-phenomena of the three elements; and the importance of their examination was urged, not alone as a means of eliminating their influence on the periodic and progressive changes, but also on the independent ground, that "the theory of the transitory changes might prove itself one of the most interesting and important points to which the attention of magnetic inquirers can be turned, as they are no doubt intimately connected with the general causes of terrestrial magnetism, and will probably lead us to a much more perfect knowledge of those causes than we now possess."

The feature which has been referred to as furnishing the principal if not the only certain characteristic of a disturbance of this class, viz., the magnitude of the departure from the usual or normal state at the instant of observation, has, in the discussion of the observations, been made available for the investigation of their laws: it has afforded the means of recognizing and separating from the entire mass of hourly observations, taken during several years, a sufficient body of observations to furnish the necessary data for investigating at three points of the earth's surface—one in the temperate zone of the northern hemisphere, a second in the temperate zone of the southern hemisphere, and a third in the tropics—the laws or conditions regulating or determining the occurrence of the magnetic disturbances. The method by which this separation has been effected has been explained on several recent occasions, and will be found. fully described in the Phil-**VI. II.**— $\mathbf{F}^*$ 

Trans. for 1856, Art. XV. By a process of this description, the disturbances of principal magnitude in each of the three elements, the Declination, Inclination and Total Force, have been separated from the other observations, at the three Observatories of Toronto, Hobarton, and St. Helena, and submitted to an analysis of which the full particulars will be found in the preliminary portions of the volumes which record the observations. By the adoption of a uniform magnitude as constituting a disturbance throughout the whole period comprised by the analysis, the amount of disturbance in the several years, months, and hours, is rendered intercomparable. The result of this investigation (which could not be otherwise than a very laborious operation, since the observations at a single one of these stations, Toronto, considerably exceeded 100,000 in number, each of which had to be passed through several distinct processes.) has made known to us that the phenomena of this class, which may in future with propriety and advantage receive the sppellation of "occasional," are, in their mean or average effects, subject to periodical laws of a very systematic character; placing them, as a first step towards an sequaintance with their physical causes, in immediate connexion with the sun as their primary exciting cause. They have-1, a diurnal variation which follows the order of the solar hours, and manifests therefore its relation to the sun's position as affected by the earth's rotation on its axis; 2, an annual variation, connecting itself with the sun's position in regard to the ecliptic; and 3, a third varia+ tion, which seems to refer still more distinctly to the *direct* action of the sun, since, both in period and in epochs of maximum and minimum, it coincides with the remarkable solar period of about ten, or perhaps more nearly eleven, of our years, the existence of which period has been recently made known to us by the phenomena of the solar spots; but which, as far as we yet know, is wholly unconnected with any thermic or physical variation of any description (except magnetic) at the surface of the earth, and equally so with any other cosmical phenomena with which we are acquainted. The discovery of a connexion of this remarkable description, giving apparently to magnetism a much higher position in the scale of distinct natural forces than was previously assigned to it, may justly be claimed on the part of the Colonial Observatories, as the result of the system of observation enjoined (and so patiently and carefully maintained), and of the investigation for which it has supplied the data; since it was by means of the disturbance-variations so determined, that the coincidence between the phenomena of the solar spots and the magnitude and frequency of magnetic disturbances was first perceived and announced (Phil. Trans. 1852, Art. VIIL)

The extent and mutual relation of the disturbance-variations of the three elements, even at a single station, supply a variety of points of approximation and of difference, which are well suited to elucidate the physical causes of these remarkable phenomena; but valuable as such aids may be when obtained for a single station, their value is greatly augmented when we are enabled to compare and combine the analogous phenomena, as they present themselves at different points of the earth's surface. To give but a single example :—there are certain variations produced by the mean effects of the disturbances which attain their maximum at Toronto during the hours of the night; the corresponding variations attain their maximum, at Hobarton, also during the hours of the night, but with a small systematic difference as to the precise hour, and with this distinguishing peculiarity, that the deflection at Hobarton is of the opposite pole of the needle (or of the same pole in the opposite direction,) to the Toronto disturbance; whilst

at a third station, St. Helena, which is a tropical one, the hours of principal disturbance are those not of the night, but of the day. A very superficial examination is sufficient to show that for the generalization of the facts,—a generalization which is indispensable for their correct apprehension and employment in the formation of a theory,—the stations at which the phenomena are to be known must be increased. Those which were chosen for a first experiment were well selected to prove the importance of the investigation, and thus to lead to its extension. It is only at the Colonial Observatories that the disturbance-variations have hitherto been made out; and taking experience as our guide, we have before us the evidence of the means by which the inquiry may be further successfully prosecuted.

Periodical Variations .- The anticipation expressed in the Report of the Committee of Physics, that for the purpose of obtaining a correct knowledge of the regular periodical variations, it would be found necessary to eliminate the "casual nerturbations," has been fully confirmed. Had the latter been strictly "casual" (or accidental, in a sense contradistinguished from and opposed to periodical), a sufficiently extended continuance of observation might have occasioned their mutual compensation ; but now that we have learned that the mean effects which they produce are governed by periodical laws, and that these laws and those of the regular periodical variations are dissimilar in their epochs, it is manifest that in their joint and undivided effects we have two variations, due to different causes and having distinct laws, superimposed upon each other; to know the one correctly we must necessarily therefore eliminate the other. A striking illustration of the importance of such elimination is furnished by the solar-diurnal variation of the total force. It will readily be imagined that the question must be an important one, whether a variation, which is supposed to derive its origin from the sun, be a single or a double progression; whether it have two maxima and two minima in the twenty-four hours, or but one maximum and one minimum in that period. When no separation is made of the disturbances, the progression appears to be a double one, having two minima, one occurring in the day and the other in the night, With the removal of the disturbed observations the night minimum disappears, and we learn that the regular solar-diurnal variation of the total force has but one notable inflection in the twenty-four hours, viz., that which takes place during the hours when the sun is above the horizon. The night minimum is in fact the mean effect of the occasional disturbances. It is probable that the nocturnal inflection of the solar-diurnal variation of the Declination may be ascribed to the same cause, namely to the superposition of two distinct variations.

A careful analysis of the solar-diurnal variations of the Declination at the Colonial Observatories has brought to light the existence at all these stations, of an *annual inequality* in the direction of the needle concurrent with changes in the sun's declination, having its maxima (in opposite directions) when the sun is in or near the opposite solstices, and disappearing at or near the epochs of the equinoxes. An intercomparison of the results of the analysis at these stations has shown, that this inequality has the remarkable characteristic of having notably the same direction and amount in the southern as in the northern hemisphere, and in the tropical as in the temperate zones. An ingenious explanation of the phenomena has been suggested by Dr. Langberg of Christiana (Proceedings of the Royal Society, vol. vii., p. 434); but whether this explanation be or be not the correct one, the theoretical importance of the facts cannot be doubted, inasmuch as they appear to be wholly irreconcileable with the hypothesis which would attribute the magnetic variations to thermic causation. We may ascribe to the general and almost exclusive prevalence of the thermic hypothesis, and to its influence on magnetic reasonings, that the well-known erroneous opinion was so confidently promulgated by a deservedly high magnetic authority, that a line *must* exist surrounding the globe, in which the needle would be found to have *no diurnal variation*. We have now, on the contrary, reason to be assured, by the facts of the annual inequality thus discovered, that there is no such line; but that everywhere in the regions of its supposed existence a diurnal variation subsists, having opposite characteristics in opposite parts of the year as influenced by the sun's position on either side of the equator, and disappearing only at the epochs when the sun passes from south to north or from north to south Declination.

Lunar Variation .- But if thermic relations have failed to supply a connecting link between the sun and those magnetic variations which are, without doubt, referable to the sun as their primary cause, the failure of that hypothesis is made still more obvious by the existence of variations governed by the moon's position relatively to the place of observation. We are indebted to M. Kreil, now holding the same position in Austria that I have filled in England, for the first suggestion of the existence of a lunar-diurnal variation of one of the elements, viz., of the Declination, founded on observations at Milan and Prague; and in the Phil. Trans. for 1856, Art. XXII., will be found an exposition of the facts of the moon's diurnal influence on each of the three magnetic elements at Toronto, viz., on the Declination, Inclination and Total Force. In the case of this investigation, notwithstanding the smallness of the values concerned, the instrumental means supplied to the Colonial Observatories have been found competent to determine, with an approximation sufficient for present theoretical purposes, the character and amount for each element of the regular daily effect of the moon on the terrestrial magnetic phenomena, the existence of which does not appear to have been even suspected at the time when the Report of the Committee of Physics was drawn up. The discovery of the moon's influence on any of the magnetic elements is due, as already stated, to M. Kreil; but Toronto is the first, and as yet the only, station, at which the numerical values at every lunar hour of the lunar-diurnal variations of the three elements have been published. Corresponding statements to that which has been given for Toronto, will be found for St. Helena and Hobarton, in the volumes of those observatories, which are now in preparation. All the results at the three stations present the same general characters. The lunar influence does not appear to participate in the decennial inequality which is found in all the solar variations (Phil. Trans. 1857, Art. I.). The lunar-diurnal variation of each of the elements is a double progression in the twenty-four hours, having epochs of maximum and minimum symmetrically disposed. In character, therefore, it differs from what might be expected to take place if the moon were possessed of inherent magnetism, i. e. if she were a magnet, as it is usually termed, per se; and accords with the phenomena which might be expected to follow if she were magnetic only by induction from the earth. On the other hand, it is believed that the amount of the variation, as observed at each of these stations, very far exceeds what can be imagined to proceed from the earth's inductive action reflected from the moon. In this theoretical difficulty we are naturally thrown back to seek a more extensive knowledge of the phenomena than we have yet obtained, and to the generalization which will follow, when sufficient materials for it have been procured. In subordinate particulars, a difference, which is apparently systematic

is perceived to exist in regard to the hours which constitute the epochs of maxima and minima at the three stations, as well as in regard to the amounts of the respective variations; these differences are no doubt intimately connected with the causes of the phenomena, and are likely to lead to their elucidation.

The domain of periodical variations has thus been considerably enlarged since the Report of the Committee of Physics was drawn up; and must henceforth be understood to comprise, in addition to the variations "whose amount is a function of the hour-angle of the sun, and of his longitude" (or of his declination) (Report, p. 10),—1stly, those variations of the three elements whose amount is a function of the hour-angle of the moon; 2ndly, those variations which were classed in the Committee's Report as "irregular," or " apparently observing no law," but which are now known to be governed by laws depending on the sun's declination, and hour-angle; and 3rdly, those variations, both "irregular" and "occasional," which have their epochs and amounts dependent apparently on a solar period of not yet perfectly ascertained duration, manifesting itself also by periodical changes in the frequency and amount of the solar spots.

Absolute Values and Secular Changes .- But interesting and valuable as is the acquisition of a fuller and more precise knowledge of the comparatively small magnetic variations produced at the surface of the earth by the action or influence of external bodies, even greater importance seems to attach,-when terrestrial magnetism is in question,-to the purposes of that distinct branch of the duties of a magnetic observatory, which consists in the determination of the absolute values and secular changes of the three magnetic elements. By the absolute values we seek to acquire a knowledge of the actual present order and distribution of the terrestrial magnetic influence at the surface of the earth, and to provide the materials by which the constancy, or otherwise, of the earth's magnetic charge may hereafter be examined; and by determinations of the present direction and amount of the secular changes, we seek to become acquainted with the laws, and ultimately with the causes, of that most mysterious change, by which the magnetic condition of the globe at one epoch passes progressively and systematically into that of another. It is specially by determinations of this class, obtained with the necessary precision in different parts of the globe, that, in the words of the Committee's Report, "the patient inductive inquirer must seek to ascend to the general laws of the earth's magnetism." At the time when the Report of the Committee of Physics was written, doubts were reasonably entertained, whether the limited time, during which the Colonial Observatories were likely to be maintained in action, would be sufficient for the determination of the secular changes ; and it was therefore very properly argued, that these changes cannot be concluded from comparatively short series of observations without giving to the observations extreme nicety, so as to determine with perfect precision the mean state of the elements at the two extremes of the period embraced. It is with much satisfaction, and with a well deserved recognition of the pains which have been bestowed by the successive directors of the Toronto Observatory, and their assistants, on this branch of their duties, that I am able to refer to the determinations of the absolute values and secular changes of the three elements contained in the third volume of the Toronto observations, in evidence that the instrumental means which were devised, and the methods which have been adopted, have proved, under all the disadvantages of a first essay, sufficient to determine these data with a precision which is greatly in advance of preceding experience, and, as far as may be judged, equal to the present requirements of theoretical investigation. This is the more deserving of notice, because Toronto is a station where the casual and periodical variations, which it was apprehended would seriously interfere with the determination of absolute values, are unusually large. We may derive, therefore from the results thus obtained, the greatest encouragement to persevere in a line of research which is no longer one of doubtful experiment, and to give it that further extension which the interests of science require.

Amongst the results which have recompensed the labours of the Colonial Observatories in this branch of their inquiries, perhaps there is none of more importance in respect to the general theory of terrestrial magnetism, than the conclusion which has been established by means of the observations of the Declination at St. Helena, that the current annual amount of secular change takes place by equal aliquot portions in every month, and even in every fortnight of the year. The magnitude of the annual change of the Declination at St. Helena, 8' (or more precisely 7'-93 in each of the eight years in which the observations were maintained), and the comparative tranquillity of the tropical regions in regard to magnetic disturbances, were circumstances which rendered St. Helena a particularly eligible locality for an investigation of this nature. The result has been, to remove secular change altogether from the category of atmospheric or thermic relations, with which, in the absence of a correct knowledge of the facts, it has frequently been erroneously associated; and to show conclusively that it is a phenomenon of far more systematic order and regularity than has been generally apprehended (Proceedings of the Royal Society, vol. vii. pp. 67-75).

### THE BRITISH ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

One of the most brilliant and successful meetings which have signalized the progress of the British Association in the accomplishment of its important aims, opened at Dublin on the 26th of August. Twenty-two years have elapsed since last the Association graced the halls of the Irish Capital : and great as are the changes every where noticeable in such a lapse of time, a more momentous epoch has not occurred in the history of Ireland. To whatever city the Association returns after such an interval, the survivors who bore a part in its deliberations and discussions, must recall many former valued coadjutors now no more ; while also the hopeful and cheering element is not wanting. The eager boy who then gratified his vague longings by a stolen peep into the sections, is now seen entering as a scientific cadet, and doing duty on the local committee, or honored with a special and recognized rank as a secretary of his favourite section ; while again the youthful sectional secretary of former years, now steps down into the arena, acknowledged as an equal among the veterans of science.

After the usual preliminary business, including the reading of the Report of the Council to the General Committee, and the presentation of the reports of the Kew Observatory, the Parliamentary Committee, and the General Treasurer; the members and friends of the association assembled in the Rotunda, where Professor Daubeny resigned the chair to his successor, the Rev. HUMPHEEY LLOYD, D. D.

After some interesting reminiscences of a personal and local nature, with which the President opened his Address, he thus proceeded in accordance with the well approved practice of presidents of the British Association, to give an epitome of some of the most remarkable recent additions to science :

"To commence, then, with Astronomy :- The career of planetary discovery, which began in the first years of the present century, and was resumed in 1845, has since continued with unabated ardour. But since 1846 not a single year has passed without some one or more additions to the number of the planetoids ; and in one year alone (1852), no fewer than eight such bodies were discovered. The last year has furnished its quota of five, and in the present three more have been found, one by Mr. Pogson, of Oxford, and the other two by M. Goldschmidt, of Paris. The known number of these bodies is now forty-five. Their total mass, however, is very small. The diameter of the largest is less than forty miles, while that of the smallest (Atalanta) is little more than four. These discoveries have been facilitated by star-maps and star-catalogues, the formation of which they have on the other hand stimulated. Two very extensive works of this kind are now in progress-the Star Catalogue of M. Chacornac, made at the Observatory of Marseilles, in course of publication by the French Government ; and that of Mr. Cooper, made at his observatory at Markree, in Ireland, which is now being published by the help of the Parliamentary Grant of the Royal Society. It is a remarkable result of the latter labour, that no fewer than seventy-seven stars, previously catalogued are now missing. This, no doubt, is to be ascribed in part to the errors of former observations; but it seems reasonable to suppose that, to some extent at least, it is the result of changes actually in progress in the Sidereal System. The sudden appearance of a new fixed star in the heavens, its subsequent change of lustre, and its final disappearance, are phenomena which have at all times attracted the attention of astronomers. About twenty such have been observed. Arago has given the history of the most remarkable, and discussed the various hypotheses which have been offered for their explanation. Of these, the most plausible is that which attributes the phenomenon to unequal brightness of the faces of the star which are presented successively to the earth by the star's rotation round its axis. On this hypothesis the appearance should be periodic. M. Goldschmidt has recently given support to this explanation, by rendering it probable that the new star of 1609 is the same whose appearance was recorded in the years 393, 798, and 1203. Its period, in such case, is 4054 years. The greater part of the celestial phenomena are comprised in the movements of the heavenly bodies and the configurations depending on them; and they are for the most part reducible to the same law of gravity which governs the planetary motions.

"But there are appearances which indicate the operation of other forces, and which, therefore, demand the attention of the physicist—although, from their nature, they must probably long remain subjects of speculation. Of these, the spiriform nebulæ, discovered by Lord Rosse, have been already referred to from this chair, as indicating changes in the more distant regions of the universe, to which there is nothing entirely analogous in our own system. These appearances are accounted for, by an able anonymous writer, by the action of gravitating forces combined with the effects of a resisting medium—the resistance being supposed to bear a sensible proportion to the gravitating action.

"The constitution of the central body of our own system presents a nearer and more interesting subject of speculation. Towards the close of the last century many hypotheses were advanced regarding the nature and constitution of the sun,

#### BRITISH SCIENTIFIC ASSOCIATION.

all of which agreed in considering it to be an opaque body, surrounded at some distance by a luminous envelope. But the only certain fact which has been added to science in this department is the proof given by Arago that the light of the sun emanated (not from an incandescent solid, but) from a gaseous atmosphere, the light of incandescent solid bodies being polarized by refraction, while the light of the sun, and that emitted by gaseous bodies, is unpolarized. According to the observations of Schwabe, which have been continued without intermission for more than thirty years, the magnitude of the solar surface obscured by spots increases and decreases periodically, the length of the period being 11 years and 40 days. This remarkable fact, and the relation which it appears to bear to certain phenomena of terrestrial magnetism, have attracted fresh interest to the study of the solar surface; and, upon the suggestion of Sir John Herschel, a photoheliographic apparatus has lately been established at Kew, for the purpose of depicting the actual macular state of the sun's surface from time to time. It is well known that Sir William Herschel accounted for the solar spots by currents of an elastic fluid ascending from the body of the sun, and penetrating the exterior luminous envelope. A somewhat different speculation of the same kind has been recently advanced by Mosotti, who has endeavoured to connect the phenomena of the solar spots with those of the red protuberances which appear to issue from the body of the sun in a total eclipse, and which so much interested astronomers in the remarkable eclipse of 1842.

"Next to the sun, our own satellite has always claimed the attention of astronomers, while the comparative smallness of its distance inspired the hope that some knowledge of its physical structure could be attained with the large instrumental means now available. Accordingly, at the meeting of the Association held at Belfast in 1852, it was proposed that the Earl of Rosse, Dr. Robinson, and Prof. Phillips, be requested to draw up a Report on the physical character of the moon's surface, as compared with that of the earth. That the attention of those eminent. observers has been directed to the subject, may be inferred from the communication lately made by Prof. Phillips to the Royal Society on the mountain Gassendi, and the surrounding region. But I am not aware that the subject is yet ripe for a Report. I need not remind you that the moon possesses neither sea nor atmosphere of appreciable extent. Still, as a negative, in such case, is relative only to the capabilities of the instruments employed, the search for the indications of a lunar atmosphere has been renewed with every fresh augmentation of telescopic power. Of such indications, the most delicate, perhaps, are those afforded by the occulta. tion of a planet by the moon. The occultation of Jupiter, which took place on the 2nd of January last, was observed with this reference, and is said to have exhibited no hesitation, or change of form or brightness, such as would be produced by the refraction or absorption of an atmosphere. As respects the sea, the mode of examination long since suggested by Sir David Brewster is probably the most effective. If water existed on the moon's surface, the sun's light reflected from it should be completely polarized at a certain elongation of the moon from the sun. No traces of such light have been observed; but I am not aware that the observations have been repeated recently with any of the larger telescopes. It is now well understood that the path of astronomical discovery is obstructed much more by the earth's atmosphere than by the limitation of telescopic powers. Impressed with this conviction, the Association has, for some time past, urged upon Her Majesty's Government the scientific importance of establishing a large reflector at

some elevated station in the Southern Hemisphere. In the mean time, and to gain (as it were) a sample of the results which might be expected from a more systematic search, Prof. Piazzi Smyth undertook, last summer, the task of transporting a large collection of instruments—meteorological and magnetical, as well as astronomical—to a high point on the Peak of Teneriffe. His stations were two in number, at the altitudes above the sea of 8,840 and 10,700 feet respectively; and the astronomical advantages gained, may be inferred from the fact, that the heat radiated from the moon, which has been so often sought for in vain in a lower region, was distinctly perceptible, even at the lower of the two stations.

"The researches relative to the Figure of the Earth and the Tides are intimately connected with Astronomy, and next claim our attention. The results of the Ordnance Survey of Britain, so far as they relate to the earth's figure and mean density, have been lately laid before the Royal Society by Col. James, the Superintendent of the Survey. The ellipticity deduced is  $\frac{1}{209^{1/33}}$ . The mean specific gravity of the earth, as obtained from the attraction of Arthur's Seat, near Edinburgh, is 5316; a result which accords satisfactorily with the mean of the results obtained by the torsion balance. Of the accuracy of this important work, it is sufficient to observe, that when the length of each of the measured bases (in Salisbury Plain and on the shores of Lough Foyle) was computed from the other, through the whole series of intermediate triangles, the difference from the measured length was only 5 inches in a length of from 5 to 7 miles.

"Our knowledge of the laws of the Tides has received an important accession in the results of the tidal observations made around the Irish coasts in 1851, under the direction of the Royal Irish Academy. The discussion of these observations was undertaken by Prof. Haughton, and that portion of it which relates to the diurnal tides has been already completed and published. The most important result of this discussion is the separation of the effects of the sun and moon in the diurnal tide-a problem which was proposed by the Academy as one of the objects to be attained by the contemplated observations, and which has been now for the first time accomplished. From the comparison of these effects Prof. Haughton has drawn some remarkable conclusions relative to the mean depth of the sea in the Atlantic. In the dynamical theory of the tides, the ratio of the solar to the lunar effect depends not only on the masses, distances, and periodic times of the two luminaries, but also on the depth of the sea; and this, accordingly, may be computed when the other quantities are known. In this manner Prof. Haughton has deduced from the solar and lunar co-efficients of the diurnal tide, a mean depth of 5.12 miles—a result which accords in a remarkable manner with that inferred from the ratio of the semi-diurnal co-efficients, as obtained by Laplace from the Brest observations. The subject, however, is far from being exhausted. The depth of the sea, deduced from the solar and lunar tidal intervals, and from the age of the lunar diurnal tide, is somewhat more than double of the foregoing; and the consistency of the individual results is such as to indicate that their wide difference from the former is not attributable to errors of observation. Prof. Haughton throws out the conjecture that the depth, deduced from the tidal intervals and ages, orresponds to a different part of the ocean from that inferred from the heights.

"The phenomena of *terrestrial magnetism* present many close analogies with those of the tides; and their study has been, in a peculiar manner, connected with the labours of this Association. To this body, and by the hands of its present general secretary, were presented those reports on the distribution of the

#### BRITISH SCIENTIFIC ASSOCIATION.

terrestrial magnetic force which re-awakened the attention of the scientific world to the subject. It was in the Committee rooms of this Association that the first step was taken towards that great magnetic organization which has borne so much fruit. It was here that the philosophical sagacity of Herschel guided its earlier career; and it was here again that the cultivators of the science assembled, from every part of Europe, to deliberate about its future progress. It was natural therefore, that the results obtained from such beginnings should form a prominent topic in the addresses which have been annually delivered from this chair ; and the same circumstances will plead my excuse if I now revert to some of them which have been already touched upon by my predecessors. It has been long known that the elements of the earth's magnetic force were subject to certain regular and recurring changes, whose periods were, respectively, a day and a year, and which, therefore, were referred to the sun as their source. To these periodical changes Dr. Lamont of Munich, added another of ten years: the diurnal range of the magnetic declination having been found to pass from a maximum to a minimum and back again, in about that time. But besides these slow and regular changes, there are others of a different class, which recur at irregular intervals, and which are characterized by a large deviation of the magnetic elements from their normal state, and generally also by rapid fluctuation and change. These phenomena, called by Humboldt 'magnetic storms,' have been observed to occur simultaneously in the most distant parts of the earth, and thus to indicate a cause operating upon the entire globe. But, casual as they seem, these effects are found to be subject to laws of their own. Prof. Kreil was the first to discover that, at a given place, they recurred more frequently at certain hours of the day than at others; and that, consequently, in their mean effects, they were subject to periodical laws, depending upon the hour at each station. The laws of this periodicity have been ably worked out by General Sabine in his discussion of the results of the British Colonial Observatories; and he has added the important facts, that the same phenomena observe also the two other periods already noticed, -namely, the annual and the decennial periods. He has further arrived at the very remarkable result, that the decennial magnetic period coincides, both in its duration and in its epochs of maxima and minima, with the decennial period observed by Schwabe in the solar spots; from which it is to be inferred that the sun exercises a magnetic influence upon the earth dependent on the condition of its luminous envelope. We are thus in the presence of two facts, which appear at first sight opposed-namely the absolute simultaneity of magnetic disturbances at all parts of the earth, and their predominance at certain local hours at each place. General Sabine accounts for this apparent discrepancy by the circumstance, that the hours of maximum disturbance are different for the different elements; so that there may be an abnormal condition of the magnetic force, operating at the same instant over the whole globe, but manifesting itself at one place chiefly in one element, and at another place in another. I would venture to suggest, as a subject of inquiry, whether the phenomena which have been hitherto grouped together as 'occasional' effects may not possibly include two distinct classes of changes, obeying separate laws; one of them being strictly periodic, and constituting a part of the regular diurnal change; while the other is strictly abnormal, and simultaneous at all parts of the globe. If this be so, it would follow that we are not justified in separating the larger changes from the rest, merely on the ground of their magnitude, and that a different analysis of the phenomenon is required. The effects hitherto con-

sidered are all referable to the snn as their cause. Prof. Kreil discovered, however, that another body of our system—namely, our own satellite—exerted an effect upon the magnetic needle, and that the magnetic declination underwent a small and very regular variation, whose amount was dependent on the lunar hour angle, and whose period was therefore a lunar day. This singular result was subsequently confirmed by Mr. Broun in the discussion of the Makerstown Observations; and its laws have since been fully traced, for all the magnetic elements, by General Sabine, in the discussion of the results obtained at the Colonial Magnetic Observatories.

\* \* \* \* \* \* \* \* \* \* \* \*

"The most important step which has been recently taken in this country to advance the science of Meteorology has been the formation of a department connected with the Board of Trade, for the collection and discussion of meteorological observations made at sea. The practical results of a similar undertaking in the United States are now well known. The charts and sailing directions published by Lieut. Maury have enabled navigators to shorten their passages, in many cases by one-fourth of the time, and in some even to a greater extent. The commercial importance of such a result could not fail to attract general attention; and accordingly, when the United States Government invited other maritime nations to co-operate in the undertaking, the invitation was cordially accepted. A conference was held at Brussels in 1853, at which meteorologists deputed by those powers attended; and a Report was made, recommending the course to be pursued in a general system of marine meteorological observations. This Report was laid before the British Parliament soon after, and a sum of money was voted for the necessary expenditure. The British Association undertook to supply verified instruments by means of its Observatory at Kew; and the Royal Society, in consultation with the most eminent meteorologists of Europe and America, addressed an able Report to the Board of Trade, in which the objects to be attended to, so as to render the system of observation most available for science, were clearly set forth. With this co-operation on the part of the two leading scientific societies, the establishment was soon organized. It was placed under the direction of a distinguished naval officer, Admiral FitzRoy; and in the beginning of 1855 it was in operation. Agents were established at the principal ports for the supply of instruments, books, and instructions ; and there are now more than 200 British ships so furnished, whose officers have undertaken to make and record the required observations, and to transmit them from time to time to the Department. The observations are tabulated, by collecting together, in separate books those of each month, corresponding to geographical spaces bounded by meridians and parallels 10 degrees apart. At the present time, 700 months of logs have been received from nearly 100 merchant ships, and are in process of tabulation. Holland is taking similar steps; and the Meteorological Institute of that country, under the direction of Mr. Buys Bellot, has already published three volumes of nautical information, obtained from Dutch vessels in the Atlantic and Indian Oceans. For the purposes of meteorological science, this system cannot be considered as complete until observations on land are included. Most of the greater atmospheric changes are due to the distribution of land and water, and to the different effects of the sun's rays on each Observation alone can furnish the data from which the effects of these agencies may be calculated; and we can therefore probably make no great advance in the knowledge of the meteorology of the globe, without a concurrent investigation of

#### BRITISH SCIENTIFIC ASSOCIATION.

its two leading departments. Land observations exist in great numbers. In Prussia, in Russia, in Austria, and in Belgium, such observations are organized under Government direction, or at least with Government support. In other parts of Europe, as in Britain, the labour is left to individuals or scientific Societies. What is needed is to give *unity* to these isolated labours—to connect them with one another, and with the results obtained at sea; and the first step to this seems to be to give them, in each country, that permanence and uniformity of system which can only be insured in measures adopted by the State.

\* \* \* \* \* \*

"The most important of the recent additions to the theory of Light have been those made by M. Jamin. It has been long known that metals differed from transparent bodies, in their action on light, in this, that plane-polarized light reflected from their surfaces became elliptically polarized; and the phenomenon is explained on the principles of the wave theory, by the assumption that the vibration of the ether undergoes a change of phase at the instant of reflexion, the amount of which is dependent on its direction and on the angle of incidence. This supposed distinction, however, was soon found not to be absolute. Mr. Airy showed that diamond reflected light in a manner similar to metals; and Mr. Dale and Prof. Powell extended the property to all bodies having a high refractive power. But it was not until lately that M. Jamin proved that there is no distinction in this respect between transparent and metallic bodies; that all bodies transform planepolarized into elliptically-polarized light, and impress a change of phase at the moment of reflexion. Prof. Haughton has followed up the researches of M. Jamin, and established the existence of *circularly polarized* light by reflexion from transparent surfaces. The theoretical investigations connected with this subject afford a remarkable illustration of one of those impediments to the progress of natural philosophy which Bacon has put in the foremost place among his examples of the Idola—I mean the tendency of the human mind to suppose a greater simplicity and uniformity in nature than exists there. The phenomena of polarization compel us to admit that the sensible luminous vibrations are transversal, or in the plane of the wave itself; and it was naturally supposed by Fresnel, and after him by McCullagh and Neumann, either that no normal vibrations were propagated, or that, if they were, they had no relation to the phenomena of light. We now learn that it is by them that the phase is modified in the act of reflection : and that, consequently, no dynamical theory which neglects them, or sets them aside, can be complete. Attention has been lately recalled to a fundamental position of the wave-theory of light, respecting which opposite assumptions have been made. The vibrations of a polarized ray are all parallel to a fixed direction in the plane of the wave; but that direction may be either parallel or perpendicular to the plane of polarization. In the original theory of Fresnel, the latter was assumed to be the fact; and in this assumption Fresnel has been followed by Cauchy. In the modified theories of McCullagh and Neumann, on the other hand, the vibrations are supposed to be parallel to the plane of polarization. This opposition of the two theories was compensated, as respects the results, by other differences in their hypothetical principles; and both of them led to conclusions which observation has verified. There seemed, therefore, to be no means left to the theorist to decide between these conflicting hypotheses until Prof. Stokes recently, in applying the dynamical theory of light to other classes of phenomena, found one in which the effects should differ on the two assumptions. When light

## 468

\* \*
is transmitted through a fine grating, it is turned aside, or *diffracted*, according to laws which the wave theory has explained. Now, Prof. Stokes has shown that, when the incident light is polarized, the plane of vibration of the diffracted ray must differ from that of the incident, the two planes being connected by a very simple relation. It only remained, therefore, for observation to determine whether the planes of polarization of the incident and refracted rays were similarly related. or not. The experiment was undertaken by Prof. Stokes himself, and he has inferred from it that the original hypothesis of Fresnel is the true one. But, as an opposite result has been obtained by M. Holzmann, on repeating the experiment. the question must be regarded as still undetermined. The difference in the experimental results is ascribed by Prof. Stokes to the difference in the nature of the gratings employed by himself and by the German experimentalist, the substance of the diffracting body being supposed to exert an effect upon the polarization of the light, which is diffracted by it under a great obliquity. I learn from Prof. Stokes that he proposes to resume the experimental inquiry, and to test this supposition by employing gratings of various substances. If the conjecture should prove to be well founded, it will greatly complicate the dynamical theory of light. In the mean time the hypothesis is one of importance in itself, and deserves to be verified or disproved by independent means.

\* \* \*

\*

\* \* \*

\*. .\* .\* "In the whole range of experimental science there is no fact more familiar, or longer known, than the development of Heat by friction. The most ignorant savage is acquainted with it,--it was probably known to the first generation of mankind. Yet, familiar as it is, the science of which it is the germ dates back but a very few years. It was known from the time of Black, that heat disappeared in producing certain changes of state in bodies, and reappeared when the order of those changes was reversed; and that the amount of heat, thus converted, had a given relation to the effect produced. In one of these changes-namely, evaporation, a definite mechanical force is developed, which is again absorbed when the vapour is restored by pressure to the liquid state. It was, therefore, not unnatural to conjecture, that in all cases in which heat is developed by mechanical action, or vice versa, a definite relation would be found to subsist between the amount of the action and that of the heat developed or absorbed. This conjecture was put to the test of experiment by Mayer and Joule, in 1842, and was verified by the result. It was found that heat and mechanical power were mutually convertible; and that the relation between them was definite, 772 foot-pounds of motive power being equivalent to a unit of heat-that is, to the amount of heat requisite to raise a pound of water through one degree of Fahrenheit. The science of Thermodynamics, based upon this fact, and upon a few other obvious facts or self-evident principles, has grown up in the hands of Clausius, Thomson, and Rankine, into large proportions, and is each day making fresh conquests in the region of the unknown. Thus far the science of heat is made to rest wholly upon the facts of experiment, and is independent of any hypothesis respecting the molecular constitution of bodies. The dynamical theory of heat, however, has materially aided in . establishing true physical conceptions of the nature of heat. The old hypothesis, : of caloric, as a separate substance, was indeed rendered improbable by the experiments of Rumford and Davy, and by the reasonings of Young; but it continued to hold its ground, and is interwoven into the language of science. It is now clearly shown to be self-contradictory; and to lead to the result that the amount of heat .

#### BRITISH SCIENTIFIC ASSOCIATION.

In the universe may be indefinitely augmented. On the other hand, the identification of radiant heat with light, and the establishment of the wave-theory, left little doubt that heat consisted in a vibratory movement either of the molecules of bodies or of the ether within them. Still, the relation of heat to bodies and the phenomena of conduction, indicate a mechanism of a more complicated kind than that of light, and leave ample room for further speculation. The only mechanical hypothesis (so far as I am aware) which is consistent with the present state of our knowledge of the phenomena of heat, is the theory of molecular vortices of Mr. Rankine. In this theory all bodies are supposed to consist of atoms. composed of nuclei surrounded with elastic atmospheres. The radiation of light and heat is ascribed to the transmission of oscillations of the nuclei ; while thermometric heat is supposed to consist in circulating currents or vortices, amongst the particles of their atmospheres, whereby they tend to recede from the nuclei, and to occupy a greater space. From this hypothesis Mr. Rankine has deduced all the laws of thermo-dynamics, by the application of known mechanical principles. He has also, from the same principles, deduce1 relations (which have been confirmed by experiment) between the pressure, density and absolute temperature of elastic fluids, and between the pressure and temperature of ebullition of fluids. The dynamical theory of heat enables us to frame some conjectures to account for the continuance of its supply, and even to speculate as to its source, The heat of the sun is dissipated and lost by radiation, and must be progressively diminished, unless its thermal energy be supplied. According to the measurements of M. Pouillet, the quantity of heat given out by the sun in a year is equal to that which would be produced by the combustion of a stratum of coal seventeen miles in thickness; and if the sun's capacity for heat be assumed equal to that of water, and the heat be supposed to be drawn uniformly from its entire mass, its temperature would thereby undergo a diminution of 2°.4 Fahr. annually. On the other hand, there is a vast store of force in our system capable of conversion into heat. If, as is indicated by the small density of the sun, and by other circumstances, that body has not yet reached the condition of incompressibility, we have, in the future approximation of its parts, a fund of heat probably quite large enough to supply the wants of the human family to the end of its sojourn here. It has been calculated that an amount of condensation, which would diminish the diameter of the sun by only the ten-thousandth part, would suffice to restore the heat emitted in 2,000 years. Again, on our own earth, vis viva is destroyed by friction in the ebb and flow of every tide, and must therefore reappear as heat, The amount of this must be considerable, and should not be overlooked in any estimation of the physical changes of our globe. According to the computation of Bessel, 25,000 cubic miles of water flow in every six hours from one quarter of the earth to another. The store of mechanical force is thus diminished and the temperature of our globe augmented by every tide. We do not possess the data which would enable us to calculate the magnitude of these effects. All that we know with certainty is, that the resultant effect of all the thermal agencies to which the earth is exposed has undergone no perceptible change within the historic period. We owe this fine deduction to Arago. In order that the date palm should ripen its fruit, the mean temperature of the place must exceed 70 ° Fahr.; and, on the other hand, the vine cannot be cultivated successfully when the temperature is 72° or upwards. Hence, the mean temperature of any place at which these two plants flourished and bore fruit must lie between these narrow

limits, i. e. could not differ from 71  $^{\circ}$  Fahr. by more than a single degree. Now, from the Bible we learn that both plants were *simultaneously* cultivated in the central valleys of Palestine in the time of Moses; and its then temperature is thus definitively determined. It is the same at the present time; so that the mean temperature of this portion of the globe has not sensibly altered in the course of thirty-three centuries.

" The future of physical science seems to lie in the path upon which three of our ablest British physicists have so boldly entered, and in which they have already made such large advances. I may, therefore, be permitted briefly to touch upon the successive steps in this lofty generalization, and to indicate the goal to which they tend. It has been long known that many of the forces of nature are related. Thus, heat is produced by mechanical action, when that is applied in bringing the atoms of bodies nearer by compression, or when it is expended in friction. Heat is developed by electricity, when the free passage of the latter is impeded. It is produced whenever light is absorbed; and it is generated by chemical action. A like interchangeability probably exists among all the other forces of nature, although in many the relations have not been so long perceived. Thus, the development of electricity from chemical action dates from the observations of Galvani; and the production of magnetism by electricity from the discovery of Oersted. The next great step was to perceive that the relation of the physical forces was mutual; and that of any two, compared together, either may stand to the other in the relation of cause. With respect to heat and mechanical force, this has been long known. When a body is compressed by mechanical force, it gives out heat; and, on the other hand, when it is heated, it dilates, and evolves power. The knowledge of the action of electricity in dissolving the bonds of chemical union followed closely upon that of the inverse phenomenon; and the discovery of electro-magnetism by Oersted was soon followed by that of magnetoelectricity by Faraday. With reason, therefore, it occurred to many minds that the relations of any two of the forces of nature were mutual-that that which is the cause, in one mode of interaction, may become the effect, when the order of the phenomena is changed ;---and that, therefore, in the words of Mr. Grove, one of the able expounders of these views, while they are "correlative," or reciprocally dependent, " neither, taken abstractedly, can be said to be the essential cause of the other." But a further step remained to be taken. If these forces were not only related, but mutually related, was it not probable that the relation was also a definite one? Thus, when heat is developed by mechanical action, ought we not to expect a certain definite proportion to subsist between the interacting forces, so that if one were doubled or trebled in amount, the other should undergo a proportionate change? This anticipation, it has been already stated, has been realized by Mayer and Joule. The discovery of the mechanical equivalent of heat has been rapidly followed by that of other forces; and we now know not only that electricity, magnetism, and chemical action, in given quantities, will produce each a definite amount of mechanical work, but we know further-chiefly through the labours of Joule-what that relation is, or, in other words, the mechanical equivalent of each force. The first step in this important career of discoverythough long unperceived in its relation to the rest-was, undoubtedly, Faraday's great discovery of the definite chemical effect of the voltaic current. The last will probably be to reduce all these phenomena to modes of motion, and to apply to them the known principles of dynamics, in such a way as not only to express

the laws of each kind of movement, as it is in itself, but also the connexion and dependence of the different classes of the phenomena. \* \* \* \* \* \* \* \*

"The science of Geology appears, of late years, to have entered upon a new phase of its development,—one characterized by a stricter reference of its speculative views to the principles of those sciences with which it is connected, and upon which it ought to be based. We have an example of this in the able Memoirs of Mr. Hopkins, on what may be called Dynamical Geology, including the changes which have taken place in the earth's crust by the operation of internal forces. Another instance of application of sound physical principles to this science is found in the explanations which have been recently offered of the phenomena of slaty cleavage. A report on this interesting subject was presented to the Association by Prof. Phillips at its last meeting, and will be found in the volume just published. These sounder views originate, I believe, with himself and with Mr. Sharpe: but they have been enlarged and confirmed by Mr. Sorby, Dr. Tyndall, and Prof. Haughton. We have another interesting proof of the readiness of geologists of the present day to submit their views to the test of exact observation, in the measurements undertaken by Mr. Horner for the purpose of approximating to the age of sedimentary deposits. Of the geological changes still in operation, none is more remarkable than the formation of deltas at the mouths of great rivers, and of alluvial land by their overflow. Of changes of the latter kind, perhaps the most remarkable is the great alluvial deposit formed in the valley of the Nile by the annual inundations of that river; and here it fortunately happens that history comes to the aid of the geologist. These sedimentary deposits have accumulated round the bases of monuments of known age; and we are, therefore, at once furnished with a *chronometric scale* by which the rate of their formation may be measured. The first of the series of measurements undertaken by Mr. Horner was made with the co-operation of the Egyptian Government, around the obelisk of Heliopolis, a monument built, according to Lepsius, 2300 years B. C. A more extensive series of researches has been since undertaken in the district of Memphis; but Mr. Horner has not yet, I believe, published the results. The problems now to be solved in *Palcontology* are clearly defined in the enunciation of the problem recently proposed by the French Academy of Sciences as one of its prize questions, viz. : 'to study the laws of distribution of organic beings in the different sedimentary rocks, according to the order of their superposition; to discuss the question of their appearance or disappearance, whether simultaneous or successive; and to determine the nature of the relations which subsist between the existing organic kingdom and its anterior states.' The prize was obtained by Prof. Bronn, of Heidelberg; and his memoir, of which I have only seen an outline, appears to be characterized by views at once sound and comprehensive. The leading result seems to be, that the genera and species of plants and animals which geology proves to have existed successively on our globe, were created in: succession, in adaptation to the existing state of their abode, and not transmuted or modified, as the theory of Lamarck supposes, by the physical influences which surrounded them."

Having embraced in his address a review of some of the most remarkable evidences of recent progress in science, Dr. Lloyd devoted the concluding portion of his speech to the administrative measures of the Association, in so far as these have a direct bearing on the advancement of its highest objects. The steps already

472

\* \*

taken for the preparation of a catalogue of papers occurring in the Transactions of the Scientific Societies and in Scientific Journals, were noted by him, and commended to the attention of the General Committee. The still more important subject of guiding the influence of the British Government and of Parliament, for improving the position of British Science, and advancing the just interests and claims of its students, next occupied his attention. The establishment of **a** Scientific Board for the control and expenditure of the public funds devoted to science; and the provision of a central National Building in the British Metropolis, for the meetings and other requirements of the principal Scientific Societies, were specially noted by the President, as objects now aimed at, and towards the accomplishment of which Her Majesty's Government have evinced a gratifying readiness to render every aid consistent with the other claims, which war and rebellion have recently made so preeminent.

Finally, Dr. Lloyd congratulated the Association on the extension of their field of labours, by the enlargement of the scope of the statistical section so as to embrace economic science in all its relations; and concluded in these words: "I am conscious that the sketch of the recent progress of the Physical Sciences, which I have endeavoured to present, is but a meagre and imperfect summary of what has been accomplished; but it is enough, at all events, to prove that science is not on the decline, and that its cultivators have not been negligent in their high calling. I now beg in the name of the local members of this body, to welcome you warmly to this city; and I pray that your labours here may redound to the glory of God, and to the welfare and happiaess of your fellow-men."

## AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

Among the features of the American Scientific Congress, in the Capitol at Albany, last year, which were felt alike by Americans and Strangers as giving a novel interest to that meeting, was the Canadian deputation sent to invite the representatives of the Science of the United States to step beyond their political bounds, and accept the hospitality of Montreal. Other, and older claims were at the same time advanced. Baltimore was especially urgent, and refused to hear of delay; but a spirit of liberal cosmopolitanism prevailed, and the invitation was accepted, which has this year enabled us to witness the honored veterans of American Science welcomed with no stinted cordiality to the chief city of the Canadas, the commercial metropolis of British America. The duties which thereby devolved on the citizens of Montreal, and on the Province at large, were neither few nor trivial; and to most of these duties past experience could lend us little aid. Nevertheless, what hearty earnestness and cordial good-will could accomplish was done; and though the occasion may not have passed off without some of those little jealousies and slights to which all such large and miscellaneous congresses are every. where liable, we have reason to believe that the general impression remaining on the minds of those who took a part in the meeting, is one of unalloyed pleasure; while the conviction has been frankly expressed by those longest and most intimately conversant with the proceedings of the American Association, that the success of the meeting was as gratifying to the assembled representatives of American Science, as it was creditable to the citizens of Montreal.

VOL. II.---G\*

The opening meeting was graced by proceedings of a cordial and hearty geniality, well suited to the occasion. His Excellency, Sir William Eyre, the Administrator of the Government, occupied the right hand of the chair. The lamented death of the President elect, Professor Bailey, devolved the inaugural duties on the Vice-President, Professor Caswell; and his graceful urbanity, ready tact, and conciliatory equanimity, were felt not only on this occasion, but throughout the meeting, to contribute not a little to the uninterrupted harmony which constituted one of the chief elements of its success. Professor Hall, of Albany, the retiring President, having introduced Professor Caswell, resigned the chair to him ; and the new President thereupon proceeded to address the members of the Association, congratulating them on the large attendance, and the happy circumstances under which they there met. "It augurs well for the interests of Science," he observed, "that so many have come here to place their choicest contributions on her altar, and to welcome to her fellowship the humblest laborer in her cause. I think also, that it is a matter of congratulation that we have met beyond the limits of the United States. However it may have been in former times, it is not now the case that :--

> "Lands intersected by a narrow frith Abhor each other; or mountains interposed . Make enemies of nations."

It is one of the felicities of our time, that in the onward march of Science, little account is taken of the boundaries that separate states and kingdoms. The discoverer of a new law or principle in nature, of a new process in the arts, or a new instrument of research, is speedily heralded over land and ocean; is welcomed as the benefactor of his race; and is immediately put into communication with the whole civilized world. We have before us a practical illustration of the amenities of science. We of the United States are here convened on British soil, little thinking that we have passed the boundary of the protection of American law, or that amidst the generous hospitality of this enterprising commercial capital of a noble Province of Great Britain, we are aliens to the British constitution. We have left the American eagle, but we feel in no danger of being harmed by the British lion. I have said that we are aliens to the British constitution ; but that must be taken in the narrowest and most technical sense, for I am proud to say, on deliberate conviction, that nothing is alien to the British constitution that looks to the perfection of knowledge, to the furtherance of the arts or the amelioration of the condition of humanity. And, further, the proudest achievements of British arms,-and they have been proud enough for the highest desires of ambition or of glory,-have been less glorious than that generous patronage of science. that success in the arts, and those efforts to improve the condition of our race, which have placed Old England in the van of the nations; and at no period of her long history has that patronage been more wisely directed, or those noble efforts more earnestly persevered in, than under the reign of the present illustrious sovereign, whose virtues are alike the ornament of her sex and her crown."

Addresses of welcome were then delivered by His Excellency, the Administrator of the Government, on behalf of the Province; by Sir William Logan, for the Local Committee and the citizens of Montreal; and by Dr. Dawson, the Principal of McGill College, as President of the Natural History Society.

To those who are familiar with the recognised sectional divisions which so largely contribute alike to the interest and the efficiency of the British Association, the

desire manifested by the American men of Science to maintain as nearly as possible an undivided action throughout, is only less surprising than their transference to a daily General Meeting, so many questions of detail which we have been accustomed to see disposed of by a Committee. In the British Association there are now seven sections in full and efficient operation ; while the American Association,-divided till last year only into a Natural History and a Physical Science Section, required that the Ethnologists, when craving at this meeting a separate one for themselves, should produce ten papers ready for reading before they could even be allowed to organise themselves into a dependent sub-section. Nevertheless it was apparent that materials were not wanting for a much more extensive organization of sections and classification of subjects; as indeed became abundantly manifest when chemistry, statistics, and political economy, all claimed to be received by the Ethnological sub-section, as orphan sciences elsewhere upprovided for. Nothing, we believe, would be found more calculated to increase at once the popular interest and the practical efficiency of the Association, than its subdivision into more numerous sections for daily work. It would indeed of necessity diminish the crowd of miscellaneous auditors. But to compel the Chemist to submit his papers to an impatient auditory of Geologists, or the Political Economist or Statistician to intrude himself on unwilling Ethnologists, is to impede the work of all, and to drive the intruding sciences to seek a heartier recognition on some other arena. Some of the characteristics which specially distinguish the organization and procedure of the American Association, are undoubtedly traceable to the circumstances in which it originated. Formed at first solely as an Association of American Geologists, the other sciences have been admitted into favour chiefly in so far as they had a bearing on the favorite study; and hence its Natural History has been to a great extent paleeontological; its Chemistry has been mineralogical or atmospheric; and Physics with Mathematics have alone heretofore secured an independent footing.

The address of the retiring President, Professor Hall, was devoted exclusively to the elucidation of his views on some novel but highly interesting questions in his own favorite science of Geology. In this he presented at great length, and with much ability, very comprehensive generalizations relative to the rise of continents, the direction and influence of currents of deposition, and the causes in operation in the formation of mountain chains. This address was originally delivered at a Conversazione given to the members of the Association by the Natural History Society of Montreal in the Bonsecours Hall. But, notwithstanding the chivalrous promptness with which the American asserts the rights and the intellectual equality of woman, it was felt by the more enthusiastic devotees of science that the gay assembly of ladies which graced the entertainment supplied an audience who might not perchance enter with all their enthusiasm into the abstruse geological questions they were challenged to discuss. Some slight dissatisfaction was accordingly expressed by a few of the more eager militant geologists who, while longing to break a lance in the lists, were too much bent on the combat al'outrance, to look with favor on bright eyes and fair faces crowding the arena. The difficulty was at length solved by Professor Hall being invited to re-deliver his address before the general meeting on a subsequent day. Its length, however, precluded the desired discussion even then; and we regret the impossibility of embracing any adequate epitome of its comprehensive generalizations within the limits at our command.

## SECTION OF GEOLOGY AND NATURAL HISTORY.

#### ON THE VARIETIES AND MODE OF PRESERVATION OF THE FOSSILS KNOWN AS STERN-BERGLE-BY J. W. DAWSON, LL.D., PRINCIPAL OF M'GILL COLLEGE, MONTREAL.

The fossils which have been named Sternbergiæ and sometimes Artisiæ, are usually mere casts in clay or sand, having a transversely wrinkled surface, and sometimes an external coaly coating and traces of internal coaly partitions. They are found in the coal formation rocks of most countries, and very abundantly in those of Nova Scotia. Until the recent discoveries of Corda and Williamson, they were objects of curious and varied conjecture to geologists and botanists, and were supposed to indicate some very extraordinary and anomalous vegetable structure. They are now known to be casts of the piths or internal medullary cavities of trees, and the genera to which some of them belong have been pointed out. In the present paper I propose to offer some further contributions toward their history, and the geological inferences deducible from it.

In a paper communicated to the Geological Society of London, in 1846, I stated my belief that those specimens of Sternbergiæ which occur with only thin smooth coatings of coal, belonged to rush-like endogens; while those to which fragments of fossil wood were attached, presented structures resembling those of conifers. Additional specimens affording well-preserved coniferous tissue, in connection with others in a less perfect state of preservation, have enabled me more fully to comprehend the homologies of this curious structure, and the manner in which specimens of it have been preserved independently of the wood.

My most perfect specimen is one from the coal field of Pictou, cylindrical but somewhat flattened. The diaphragms or transverse partitions appear to have been continuous, though now somewhat broken. They are rather less than one-tenth of an inch apart, and are more regular than is usual in these fossils. The outer surface of the pith, except where covered by the remains of the wood, is marked by strong wrinkles, corresponding to the diaphragms. The little transverse ridges are in part coated with a smooth tissue similar to that of the diaphragms, and of nearly the same thickness. In its general aspect, the specimen perfectly resembles many of the or linary marked Sternbergiæ.

On microscopic examination the partitions are found to consist of condensed pith, which, from the compression of the cells, must have been of a firm bark-like texture in the recent plant. The wood attached to the surface is distinctly coniferous, with two and three rows of discs on the cell walls. It is not distinguishable from that of Witham, or from the specimens figured by Professor Williamson. The wood and transverse partitions are perfectly silicified, and of a dark brown colour. The partitions are coated with small colourless crystals of quartz and little iron pyrites, and the remaining spaces are filled with crystalline laminæ of sulphate of barvtes.

Unfortunately this fine specimen does not possess enough of its woody tissue to show the dimensions or age of the trunk or branch which contained this enormous pith. It proves, however, that the pith itself has not been merely dried and cracked transversely by the elongation of the stem, as appears to be the case in the Butternut, (Juglans Cinerea,) and some other modern trees; but that it has been condensed into a firm epidermis-like coating and partitions, apparently less destructible than the woody tissue which invested them. In this specimen the process of condensation has been carried much farther than in that described by Professor Williamson, in which a portion of the unaltered pith remained between the Sternbergia-cast and the wood. It thus more fully explains the possibility of the preservation of such hollow chambered piths, after the disappearance of the wood. It also shows that the coaly coating investing such detached pith casts is not the medullary sheath, properly so called, but the outer part of the condensed pith itself.

The examination of this specimen having convinced me that the structure of Sternbergiæ implies something more than the transverse cracking observed in Juglandaceæ, I proceeded to compare it with other piths, and especially with that of Cecropia Peltata, a West Indian tree, of the natural family Artocarpaceæ. This recent stem is two inches in diameter. Its medullary cylinder is three-quarters of an inch in diameter, and is lined throughout by a coating of dense whitish pith tissue, one-twentieth of an inch in thickness. This condensed pith is of a firm corky texture, and forms a sort of internal bark lining the medullary cavity. Within this the stem is hollow, but is crossed by arched partitions, convex upward. These partitions are of the same white corky tissue with the pith lining the cavity; and on their surfaces, as well as on that of the latter, are small patches of brownish large-celled pith, being the remains of that which has disappeared from the intervening spaces.

Inferring from these appearances that this plant contains two distinct kinds of pith tissue, differing in duration and probably in function, I obtained, for comparison, specimens of living plauts of this and allied families. In some of these, and especially in a "Ficus Imperialis," from Jamaica, I found the same structure; and in the young branches, before the central part of the pith was broken up, it was evident that the tissue was of two distinct kinds—one forming the outer coating and transverse partitions opposite the insertions of the leaves, and retaining its vitality for several years at least; the other occupying the intervening spaces or internodes, of looser texture, speedily drying up, and ultimately disappearing.

Another variety of the Sternbergia-like pith structure appears in a rapidly growing exogenous tree with opposite leaves, cultivated here, and I believe a species of Paullinia. In this trunk there are thick nodal partitions, and the intervening spaces are hollow and lined with firm corky pith, with its superficial portion condensed into a sort of epidermis, and marked with transverse wrinkles; a cast of which would resemble those Sternbergiæ which have merely wrinkles without diaphragms.

The trunks above noticed are of rapid growth, and have large leaves; and it is probable that the more permanent pith tissue of the medullary lining and partitions serve to equalize the distribution of the juices of the stem, which might otherwise be endangered by the tearing of the ordinary pith in the rapid elongation of the internodes. A similar structure has evidently existed in the coal formation conifers of the genus Dadoxylon, and possibly they also were of rapid growth, and furnished with very large or abundant leaves.

Applying the facts above stated to the different varieties or species of sternbergia, we must in the first place connect with these fossils such plants as the Pinites Medullaris of Witham. All are distinctly coniferous, and the differences that appear may be due merely to age, or more or less rapid growth.

Other specimens of sternbergia want the internal partitions, which may, however, have been removed by decay; and these often retain very imperfect traces, or none, of the investing wood. In the case of those which retain any portion of the wood, sufficient to render probable their coniferous character, the surfacemarkings are similar in character to those of my Pictou specimen, but often vary greatly in their dimensions, some having fine transverse wrinkles, others having these wide and coarse. Of those specimens which retain no wood, but only a thin coaly investment representing the outer pith, many cannot be distinguished by their superficial markings from those that are known to be coniferous, and they occasionally afford evidence that we must not attach too much importance to the character of their markings.

The state of preservation of the sternbergia casts in reference to the woody matter which surrounded them, presents, in a geological point of view, many interesting features. Frequently, only fragments of the wood remain, in such a condition as to evidence an advanced state of decay; while the bark-like medul, lary lining remains. In other specimens the coaly coating investing the castsends forth flat expansions on either side, as if the sternbergia had been the midrib of a long thick leaf. This appearance, at one time very perplexing to me, I suppose to result from the entire removal of the wood by decay, and the flattening of the bark, so that a perfectly flattened specimen may be all that remains of a coniferous branch nearly two inches in diameter. A still greater amount of decay of woody tissue is evidenced by those sternbergia casts which are thinly coated with structureless coal. These must, in many cases, represent trunks and branches which have lost their bark and wood by decay; while the tough, cork like, chambered pith drifted away to be imbedded in a separate state. This might readily happen with the pith of Cecropia; and perhaps that of these coniferous trees may have been more durable; while the wood, like the sap wood of many modern pines, may have been susceptible of rapid decay, and liable, when exposed to alternate moisture and dryness, to break up into those rectangular blocks, which are seen in the decaying trunks of modern conifers, and are so abundantly scattered over the surfaces of coal and its associated beds in the form of mineral charcoal.

Some specimens of sternbergia appear to show that they have existed in the interior of trunks of considerable size. The best instance of this that I have found is one from the South Joggins, which appears to show the remains of a tree a foot in diameter, now flattened and converted into coal, but retaining a distinct cast of a wrinkled sternbergia pith.

Are we to infer from these facts that the wood of the trees of the genus Dadoxylon was necessarily of a lax and perishable texture ? Its structure, and the occurrence of the heart wood of huge trunks of similar character in a perfectly mineralized condition, would lead to a different conclusion; and I suspect that we should rather regard the mode of occurrence of sternbergia as cautioning against the too general inference from the state of preservation of trees of the coal formation, that their tissues were very destructible, and that the beds of coal must consist of such perishable materials. The coniferous character of the sternbergiæ, in connection with their state of preservation, seem to strengthen a conclusion at which I have been arriving from microscopic and field examinations of the coal and earbonaceous shales, that the thickest beds of coal, at least in Eastern America, consist in great part of the flattened bark of coniferous, sigillaroid and lepidodendroid trees, the wood of which has perished by slow decay, or appears only in the state of fragments and films of mineral charcoal. This is a view, however, on which I do not now wish to insist, until I have further opportunities of confirming it by observation.

The most abundant locality of sternbergia, with which I am acquainted, occurs in the neighbourhood of the town of Pictou, immediately below the bed of erect calamities described in the Journal of the Geological Society. The fossils are found in interrupted beds of very coarse sandstone, with calcareous concretions, imbedded in a thick reddish brown sandstone. These grav patches are full of well preserved calamites, which have either grown upon them, or have been drifted in clumps with their roots entire. The appearances suggest the idea of patches of gray sand rising from a bottom of red mud, with clumps of growing calamites which arrested quantities of drift plants, consisting principally of sternbergia and fragments of much decayed wood and bark, now in a state of coaly matter too much penetrated by iron pyrites to show its structure distinctly. We thus probably have the fresh growing calamites, entombed along with the debris of the old decaving conifers of some neighbouring shore; furnishing an illustration of the truth that the most ephemeral and perishable forms may be fossilized and preserved, contemporaneously with the decay of the most durable tissues. The rush of a single summer may be preserved with its minutest striæ unharmed, when the giant pine of centuries has crumbled into mould. It is so now, and it was so equally in the carboniferous period.

#### ON FLEXURE OF STRATA IN THE BROAD-TOP COAL FIELD, PENNSYLVANIA. BY J. P. LESLIE.

In introducing the subject, Mr. Leslie stated that it had only recently come under his notice, and required more consideration for the full elucidation of all the truths which the phenomena he had to refer to tended to illustrate. Meanwhile it was of importance to call the attention of scientific geologists to such a remarkable example of flexure of strata as he had now to describe. Accordingly, availing himself of an opportunity so favorable, he had prepared a diagram of the appearance which these flexures presented, and although not so able to illustrate the aspect in question as he desired to have been, the subject represented a single fact to which he wished meanwhile to draw the attention of the Association. The diagram represented a section of the only coal bed in the broad-top region worked to any extent. He had obtained the section by studying that bed in eight or ten entries. The principal facts of the case, and patent to observation, were these: The bed itself is seven or eight feet thick, nine feet at its thickest portions, and seldom becomes less than five feet. In working this bed the greatest difficulties have been met with, in the shape of these flexures. Such details are rarely witnessed elsewhere in any consecutive series. Single instances have been found in innumerable places, but here they ocur in consecutive series, presenting a curious difficulty to the practical miner. The form which these flexures present amid their involutions, may be described as running up in an angular position, and becoming steeper and steeper, nntil they finally appear to "run out." But on examination, it is found that the top shale turns upon itself, and becomes the bottom of the flexure, with a perfectly even surface, and without any fracture. In this case, the miner is at a loss to discover where to go, and there exists no trace of the coal upwards through the rock. The appearance which these present, Mr. Leslie stated, is beautifully illustrated by a specimen which Sir William Logan has in his cabinet, derived from a Canadian locality, where it may be usefully

#### AMERICAN SCIENTIFIC ASSOCIATION,

studied by any person desirous of examining the subject. In the construction of these flexures, side-pressure is the only thing that can be thought of. A slow steady irresistible pressure seems to have been brought to bear upon the rock, alternately hard and soft, so that when brought around upon each other the soft ones have been obliged to yield to the hard ones. The bed of coal alluded to is within 100 feet of the top of the old conglomerate. Above the top shales there is a mass of fine-grained sand-stone. But the effect as exhibited in these flexures could not have been so great, but for the fact that immediately below there is a bed of fine white clay, thirty or forty feet thick. How much of these flexures are the result of the forcing forward of this fine clay is one of the practical questions to which future observations must be directed.

The seams below the one now referred to have never been opened, and accordingly have not been studied, so that it is impossible to say whether these flexures correspond with those underneath. This is unfortunate, meanwhile, because one of the questions which the practical geologist is most anxious to have solved, is how far this pressure carries itself forward in vertical lines. But as the progress of mining operations will tend to effect the desired exposure of the lower strata, geologists may be glad to have their attention directed to the subject thus early.

#### SUBSIDENCE OF THE LAND ON THE NEW JERSEY COAST.-BY PROFESSOR G. H. COOK, OF RUTGEE'S COLLEGE.

In the course of some geological examinations near the coast of Southern New Jersey, the author's attention had been called to various facts indicating a change in the relative level of the land and water at some recent period. An attentive examination of these led him to the conclusion that a gradual subsidence of the land is now in progress throughout the whole length of New Jersey and of Long Island; and from information derived from others, he was induced to think that this subsidence might extend along a considerable portion of the Atlantic coast of the United States. The occurrence of timber in the marshes and water, below tide-level, is common along their whole Atlantic shore. Almost every one familiar with shore-life had observed the remains of logs, stumps, and roots, in such places, although they had been looked upon generally as the remains of trees torn from their original place of growth by torrents, or by the necessary moving of the shores, and deposited in the places where they were found, by the ordinary action of the water. But close examination made it evident that they grew upon the spots where they are found. The stumps remain upright-their roots are still fast in the firm loamy ground which underlies the marsh, and their bark and small roots remain attached to them. The localities in which they are most abundant are such as are least liable to be affected by the violent action of the water, or of storms. Thus they are by far the most abundant on the low and gently sloping shores of Long Island, New Jersey, and all the States farther South which are protected from the violent action of the surf by a line of sand beaches, at the same time that the numerous inlets allow free access to the tides. In these protected situations hundreds and even thousands of acres can be found in which the bottom of the marshes and bays is as thickly set with the stumps of trees as is the ground of any living forest. His own observations were chiefly made upon the southern part of New Jersey, following the shores of Delaware Bay from its head down to Cape May, and the Atlantic shore from Cape May north to Great Egg Harbor,

#### GEOLOGY AND NATURAL HISTORY.

and thence eastward at several points along the south shore of Long Island. In the ditches in the marshes, above Salem, great numbers of the stumps and trunks of trees are met with at all depths, down to the solid ground. At Elsinboro' Point, a little farther down on the Delaware Bay shore, the entting away of the marsh by the water has left great numbers of stumps exposed, where they can be seen at every low tide still firmly rooted in the hard ground. They are also common in all the marshes of Cumberland County, and great numbers of them can be seen in the marshes on Main River, at Dorchester and below. In Cape May County they are seen everywhere in the marshes and the creeks, on the Delaware Bay; on the inside of Seven Mile Beach, on the sea side; and below Luckahoe, on Great Egg Harbour. In the marsh on the Raritan, above South Amboy, hundreds of them were dug out in cutting a canal across a bend in South River. The marshes on Staten Island also contain buried timber; and on Long Island, at Hempstead, and still further east, the same fact is of constant occurrence. At several places in Southern New Jersey an enormous quantity of white cedar timber is found buried in the salt marshes-sound and fit for use, and a considerable business is carried on in mining this timber and splitting it into shingles for market. At Dennisville there is a large tract of marsh underlaid by cedar swamp, earth and timber. By probing the marsh with an iron rod, the workmen find where the solid timber lies, and then removing the surface sods and roots, they manage to work in the mud and water with long one-handed saws and cut off the logs, which then rise and float, as the timber is not water-logged at all, but retains its buoyancy, and the removal of that nearest the surface releases that which is below and it rises in turn, so that a new supply is constantly coming up to the workmen. In this way a single piece of swamp which is below tide-level has been worked for fifty years past, and still gives profitable returns.

Other facts tend to the same conclusions. The owner of an extensive tract of land, between Maurice River and West Creek, informed the author that within the last fifty years he had lost 1,000 acres of timber by the tides running higher on the upland than they formerly did. On West Creek he was shown portions of upland on which good crops of wheat had been raised, within thirty years, which are now liable to be overrun by the tides. The same farm has, within the last fifty years, lost fifty acres—part wood and part cultivated land—in the same way, and taking into account all the evidence noted by himself, or set forth by others who had directed their attention to the subject, he could find no other theory which would embrace all the facts, than that of a slow and continued subsidence of the ground.

In regard to the rate at which this subsidence was going on, Professor Cook quoted the result of several examinations—three of a subsidence of three feet in 150 years, one of two feet in 100 years, two of one foot in fifty years,—and one of four inches and one of eight inches in two years. From these facts he conceived he might, with some degree of probability, set the average subsidence in the district where the observations were made, at two feet in a century, and he believed that this would also apply to all the observations yet made on the New England coasts.

ON PARTHENOGENESIS OF ANIMALS AND PLANTS-BY B. SEEMANN, F.L.S.

One of the most paradoxical questions, recently brought under the notice of men of science, is that known as the Parthenogenesis of Animals and Plants. The belief in a Parthenogenesis or *Lucina sine concubitu* is by no means of recent growth, but has arrested the attention of mankind since the earliest ages. In diving <sup>i</sup>nto the writings of the Classics, and studying the mythology of the Greeks, it will be found more than once indicated; and in searching the pages of ancient naturalists of a subsequent period, the subject frequently meets our eye; but the observations upon which such statements were founded, are of no value for the purpose of modern science.

It is different with the publications that in more recent times have been forced upon our attention, and which, having been made with all the caution, circumspection and accuracy demanded by modern criticism, have in the opinion of many eminent naturalists, completely established the fact, that there exist occasionally individual females of both animals and plants, which, in a state of virginity are able to propogate their respective species. We have no modern observations proving the existence of a Lucina sine concubitu in any of the higher animals,--at least I am not aware of any,-but few are inclined to doubt that Professor Von Siebold's works, "On Parthenogenesis in Moths and Bees," have set this question at rest as regards Insects. It is well known that Professor Richard Owen, applied the term Parthenogenesis, some years ago, to the non-sexual reproduction observable in the genus Aphis, but that process being merely one of gemmation, a budding process, equivalent to what we see in the sprouting of a plant, it is now generally rejected, and Siebold and others always understand by Parthenogenesis the Lucina sine concubitu of ancient Naturalists, and therefore lay great stress upon the distinction of true Parthenogenesis and alternation of generation. Siebold by carefully investigating the observations on Parthenogenesis in Insects, made by former naturalists, arrived at the conclusion that these observers were not sufficiently guarded against possible deceptions, and that entomologists had better reject them as inconclusive. He then shows that a true Parthenogenesis does undoubtedly exist in Psyche Helix, Solenobia clathrella, and lichenella, in Bombyx Mori, and Apis mellifica, (the Honey-bee,) but is of opinion that it occurs among insects in a much greater degree than we are at present able to prove. He places in this category the observations of Leon Dufour, that he never was able to obtain a male Diplolepis gallæ tinctariæ, and alludes to the statement of Hartig, who examined 9,000 to 10,000 individuals of Cynips divisa, and about 4,000 of Cynips folii, without ever finding among them a single male. The peculiar kind of reproduction observable in the lower Crustaceæ, which some have attempted to explain as alternation of generation or gemmation, may prove on closer investigation to be a true Parthenogenesis. Amongst the Molluscs there are also certain phenomena, which may possibly be explained as phases of a true Parthenogenesis. These allusions sufficiently show that the catalogue of reproduction in animals by means of Parthenogenesis, may be expected to receive considerable additions; whilst the doctrine hitherto generally received, that the developement of the ovum could take place solely under the direct influence of the male principle, has received a shock from which it is not likely to recover.

In the vegetable kingdom, authentic proofs of the existence of a Parthenogenesis are much more abundant than they are in the animal. Spallanzuni, seems to have been the first who, towards the close of the last century, pointed out that the female hemp did produce ripe seeds without the aid of pollen; but his statement, though confirmed by the experiments of Bernhardi, met with so much opposition that it could not obtain the acknowledgment due to it; and it is only the recent observations of Naudin in Paris, which, by confirming it still more, have at last vindicated for it the character of an accurate and strictly correct observation. Nor is it to be wondered at, that a fact, opposed to so many theories looked upon as true laws of nature, should have been received with the greatest distrust, and been, ex-cathedra, absolutely denied. That subjective deception should somewhere have taken place was a thought that readily suggested itself, as a plausible excuse for disbelieving so astounding a fact. How easy for polygamous flowers to be hidden among the female ones! (as Mr. Masters has shown them to exist occasionally in the dioicious hop plant.) How easy for pollen to be wafted to the stigmas! These and others were the objections of the unbelievers in the new discovery. To this must be added that the experiments of Koelreuter on hybrids, placed the sexuality of plants on a firmer footing than it formerly enjoyed, and that the concession that a dioicious plant could, under certain circumstances, develope its ovula without the aid of pollen, was looked upon as an absolute negation of sexuality.

The polemic on this subject was continued for many a year, but for the want of new observations began also to slacken, when on the 18th June, 1839, Mr. John Smith, Curator of the Royal Botanic Gardens at Kew, announced before the Linnean Society of London that there existed in the Royal Gardens a female specimen of a Euphorbiaccous plant, Cælebogyne ilicifolia, from New Holland, which annually produced ripe seeds without the aid of pollen. Robert Brown Lindley, the two Hookers, myself and others, subjected the Cælebogyne to strict and repeated examinations, but the result invariably was a confirmation of the case as stated by Smith. The Parthenogenesis of this plant was therefore generally accepted by the public of England; but on the Continent of Europe it was rejected,-as the observations of Treseinus on Datisca cannabina, of Lecogon Spinacia oleracea of Tenore, on Pistacia narbonensis, (confirmed by Bocconi on this and other species of Pistacia,) and of Ramisch on Mercurialis annua had already been. All these observations were regarded as mere delusions, of which science ought to be purged as speedily and completely as possibly; a fact which can take us the less by surprise when we reflect that the doctrine so ably and long maintained by the Horkelian school that the pollen contains the true origin of the embryo and that the ovulum is merely matrix-has only very recently become untenable through the experiments and observations of Hofmeister, Radlkofer and others.

It had been mentioned by Wenderoth and others that the monœcious Ricinus communis, the Castor Oil plant, produced ripe seed without the aid of pollen; but the direct observations of Naudin show that such is not the case, and that so far from exhibiting any tendency towards Parthenogenesis, all the female flowers fell off the moment the male ones were removed; a similar effect was produced on Esbalium elaterium, another monœcious plant, all the female flowers of which faded after the male ones of the same specimen were taken off: observations which justify us in considering as doubtful the existence of a Parthenogenesis in monœcious plants, but which have established it in *nine* dioicious ones belonging to seven different natural orders.

The existence of a Parthenogenesis in animals and plants throws more light upon the history of the embryo than the most able and valued physiological researches could possibly do. It shows more clearly than the most lucid explanation, that the origin of the embryo has not to be looked for in the pollen of plants, or the semen

#### AMERICAN SCIENTIFIC ASSOCIATION.

of animals, but in the ovula and ova themselves. And it is in this hin,t science recognizes the real practical utility of this great question. That the Parthenogenesis occupies an important office in the economy of nature we can already perceive, but how it comes to pass that the ova and ovula are developed without the aid of the male principle, and what means are employed to make a sexual reproduction, under such anomalous circumstances, possible, constitute one of those riddles, the solution of which is reserved for future investigation.

## QUESTIONS CONNECTED WITH THE SALTNESS OF THE SEA.\*—BY PROFESSOR CHAPMAN, OF UNIVERSITY COLLEGE, TORONTO.

It is a current opinion that, owing to the surface of the sea becoming salter and consequently heavier by evaporation, a downward motion of the surface water necessarily takes place; and hence Lieutenant Maury's hypothesis that the sea is salt in order to produce circulation. Some time ago I suggested another object in explanation of the saltness of the sea, viz, ; that the sea is salt in order to regulate evaporation. The greater the amount of salt, the slower the evaporation of the water,-and the reverse; so that, if by any easily conceivable cause, or combination of circumstances, the normal degree of saltness become either increased or diminished-a kind of self-regulating force is set up to resist the continuation of the abnormal action, until time restore the balance. Even leaving out of consideration the equalizing effects produced by the accession of fresh water to the surface of the sea by rain and rivers, it seemed to me that the principle of diffusion was in itself sufficient to prevent the sinking of the water thus affected by evaporaation; or, at least, to prevent the sinking of this water to any extent. But how to prove the point. The fact that the saltness of the open sea is substantially the same at considerable depths and at the surface, says nothing; as it would necessarily follow, that for every heavy particle of water that sunk, a lighter particle would rise up to supply its place; and hence the composition of the water would be kept uniform, without the principle of diffusion being in any way required to explain the phenomenon. After some consideration I adopted the following method, as one sufficiently trustworthy to afford an answer to the question under review :-- I procured a leaden pipe one inch in diameter, and bent into the form of the letter U; each upright being about thirty-nine inches in height, and the connecting piece at the bottom rather more than twelve inches long. This I filled up to about an inch on each side with a solution of common salt in rain water (the salt being present to the amount of 3.786 per cent.,) and then I carefully closed one end, leaving the other end open, but protected from dust by a cone of silver-paper fixed on a bent wire, and so arranged as not to prevent evaporation. The per centage of salt (3.786) was carefully ascertained, and the apparatus left in an unoccupied room, the window and door of which were kept almost constantly open, in order to promote the evaporation of the solution as much as

<sup>\*</sup> It is of course to be understood, that the term "Saltness of the sea," as here applied, has reference solely to the presence of a comparatively large amount of chloride of sodium in the water: to that principle, in fact, which constitutes the essential difference between the waters of the sea and those of lakes and rivers. The other saline substances present in variable proportions in sea-water, are present also, more or less, in bodies of fresh-water: und as they necessarily subserve the same general purposes in cach case, their consideration does not legitimately belong to the present inquiry.

possible. After the lapse of about three months, (April 18 to July 14,) portions were taken from each end of the tube, and from the connecting piece below, (a small orifice being made in this;) and the amount of salt in each portion was accurately determined. Now, if the principle of diffusion had not been brought into play, it is evident that the solution in the open limb of the tube ought to have been stronger than that in the closed limb, although, by the circulating process, the amount of salt at the top and bottom of the former might have been alike; and, again, it will be equally evident that if the principle of diffusion were brought into play, the supposed sinking of the surface solution, as the result of evaporation, must be altogether imaginary. Six separate determinations, two from each of the three portions of the tube, shewed a per centage of salt essentially the same. The following table exhibits the results obtained:

|          |                                     | Solution. | Am. of Salt. | Per ct'ge<br>of salt. |
|----------|-------------------------------------|-----------|--------------|-----------------------|
|          | ( A. From the top of the open limb  | 302.261   | 11.59        | 3.830                 |
| 1        | B. From the bottom of the same      | 300.24    | 11.51        | 3.835                 |
|          | (C. From the top of the closed limb | 288.60    | 11.055       | 3.831                 |
|          | (A. From the top of the open limb   | 264.83    | 10.16        | 3.837                 |
| <b>2</b> | - B. From the bottom of the same    | 290.10    | 11.12        | 3.833                 |
|          | (C. From the top of the closed limb | 306.66    | 11.75        | 3.832                 |

These experiments justify us, I think, in assuming that owing to diffusion, the surface waters of the sea do not become heavier than the lower strata simply by losing water by evaporation. It is quite true, that under the influence of evaporation a lowering of temperature may take place, and that an upward and downward circulation, to a certain extent, may in this manner be produced\*; but the same reasoning will apply, and with equal force, to bodies of fresh water. In conclusion, therefore, I feel justified in expressing my sustained belief, that the theory which I have proposed to account for the saltness of the son, is worthy of acceptance; this theory being that the sea is salt, essentially if not principally, in order to regulate evaporation.

Note.—Through the courtesy of various members of the American Association for the Advancement of Science, we have been favoured with abstracts of their papers, authenticated and revised reports, or, in some cases, with the loan of the original papers as submitted to the meeting in the different sections. We shall accordingly continue our report of the Montreal meeting in the next number, and endeavour to furnish a succinct embodiment of some of the most important contributions to science, presented at the first American Scientific Congress held within our Canadian frontier.

The January number of the Journal will also contain such a selection as our limited space will allow, from the numerous and valuable communications laid before the various sections during the recent meeting of the British Association for the Advancement of Science, at Dublin.

<sup>\*</sup> It should be stated that no intermixture could have taken place in the closed limb of the apparatus described above by ascending currents produced by unequal temperature, as the temperature of the lower portion of the closed tube was kept purposely lower (or at least prevented from becoming higher) than the upper portion by means of a damp rag permanently attached to it.

Rain fell on 11 days amounting to 4.171 inches; and was accompanied by thunder on three days, it was raining 45 hours 4 minutes.

A few flakes of snow fell on the 29th day, being the first this season.

The most prevalent wind was the W S W.

The least prevalent wind N.

The most windy day the 29th ; mean miles per hour 15.43.

Least windy day the 21st ; mean miles per hour 0.19.

The electrical state of the Atmosphere has indicated rather high intensity.

Ozone was in moderate quantity.

The Aurora Borealis visible on 5 nights.

## CANADIAN INSTITUTE.

## EDITING COMMITTEE:

## GENERAL EDITOR, - - - DAN. WILSON, LL.D.

I. Geology and Mineralogy: E. J. CHAPMAN, Prof. of Geology and Mineralogy, Univ. Coll. Toronto.

II. Physiology and Natural History: JAMES BOVELL, M. D., Trin. Coll., Toronto.

- III. Ethnology and Archaelogy : DANIEL WILSON, LL. D., Prof. of History and English Literature, Univ. Coll., Toronto.
- IV. Agricultural Science : H. Y. HIND, M. A., Prof. of Chemistry, Trin. Coll., Toronto.
- V. Chemistry: HENRY CROFT, D. C. L., Prof. of Chemistry, and Experimental Philosophy, Univ. Coll., (Toronto.
- VI. Mathematics and Natural Philosophy: J. B. CHERRIMAN, M. A., Prof. of Natural Philosophy, Univ. Coll., Toronto.
- VII. Engineering and Architecture: F. W. CUMBERLAND, C. E., and ALFRED BRUNEL, C. E.

The Canadian Journal is printed exclusively for gratuitous distribution among the Members of the Canadian Institute, and such Institutions and Societies as the Council may determine; but Members may purchase extra copies at 2s. 6d. per number, and Provincial Literary and Scientific Societies may obtain the Journal at the same rate, by an annual payment in advance.

\*\*\* Communications for the Journal to be addressed to the General Editor, DB. WILSON, University College, Toronto.

## TO THE READER.

"So numerous a body as the Canadian Institute now is, ought to include a much greater number of working members; and the Council are led to believe that their apparent supineness arises, in part at least, from the mistaken idea that communications can only be made in the form of elaborate essays. They, would strongly urge the encouragement of brief communications, in greater number, as at once more calculated to give general interest to the ordinary meetings, and to elicit such results of personal knowledge and observation as are best calculated to add to the true value of the published proceedings.

"Short notices of natural phenomena, features of local geology, objects of natural history, and the like subjects, derived from personal observation, must be readily producible by many members who have hitherto borne no active part in the Society's proceedings, but whose contributions would most effectually promote the objects which it is designed to accomplish."

Extract from the Annual Report of 1855.

## EDITING COMMITTEE:

### GENERAL EDITOR, - - - DAN. WILSON, LL.D.

- I. Geology and Mineralogy: E. J. CHAPMAN, Prof. of Geology and Mineralogy, Univ. Coll. Toronto.
- II. Physiology and Natural History: JAMES BOVELL, M.D., Trin. Coll., Toronto.
- III. Ethnology and Archaeology: DANIEL WILSON, LL. D., Prof. of History and English Literature, Univ. Coll., Toronto.
- IV. Agricultural Science: H. Y. HIND, M. A., Prof. of Chemistry, Trin. Coll., Toronto.
- V. Chemistry : HENRY CROFT, D. C. L., Prof. of Chemistry, and Experimental Philosophy, Univ. Coll., Toronto.
- VI. Mathematics and Natural Philosophy: J. B. CHERRIMAN, M. A., Prof. of Natural Philosophy, Univ. Coll., Toronto.
- VII. Engineering and Architecture: F. W. CUMBERLAND, C. E., and ALFRED BRUNEL, C. E.

The Canadian Journal is printed exclusively for gratuitous distribution among the Members of the Canadian Institute, and such Institutions and Societies as the Council may determine; but Members may purchase extra copies at 2s. 6d. per number, and Provincial Literary and Scientific Societies may obtain the Journal at the same rate, by an annual payment in advance.

\*\*\* Communications for the Journal to be addressed to the General Editor, DR. WILSON, University College, Toronto.

"So numerous a body as the Canadian Institute now is, ought to include a much greater number of working members; and the Council are led to believe that their apparent supineness arises, in part at least, from the mistaken idea that communications can only be made in the form of elaborate essays. They would strongly urge the encouragement of brief communications, in greater number, as at once more calculated to give general interest to the ordinary meetings, and to elicit such results of personal knowledge and observation as are best calculated to add to the true value of the published proceedings.

"Short notices of natural phenomena, features of local geology, objects of natural history, and the like subjects, derived from personal observation, must be readily producible by many members who have hitherto borne no active part in the Society's proceedings, but whose contributions would most effectually promote the objects which it is designed to accomplish."

The Canadian Journal is printed exclusively for gratuitous distribution among the Members of the Canadian Institute, and such Institutions and Societies as the Council may determine; but Members may purchase extra copies at 2s. 6d. per number, and Provincial Literary and Scientific Societies may obtain the Journal at the same rate, by an annual payment in advance.

\*\*\* Communications for the Journal to be addressed to the General Editor, DR. WILSON, University College, Toronto.

"So numerous a body as the Canadian Institute now is, ought to include a much greater number of working members; and the Council are led to believe that their apparent supineness arises, in part at least, from the mistaken idea that communications can only be made in the form of elaborate essays. They would strongly urge the encouragement of brief communications, in greater number, as at once more calculated to give general interest to the ordinary meetings, and to elicit such results of personal knowledge and observation as are best calculated to add to the true value of the published proceedings.

"Short notices of natural phenomena, features of local geology, objects of natural history, and the like subjects, derived from personal observation, must be readily producible by many members who have hitherto borne no active part in the Society's proceedings, but whose contributions would most effectually promote the objects which it is designed to accomplish."

The Canadian Journal is printed exclusively for gratuitous distribution among the Members of the Canadian Institute, and such Institutions and Societies as the Council may determine; but Members may purchase extra copies at 2s. 6d. per number, and Provincial Literary and Scientific Societies may obtain the Journal at the same rate, by an annual payment in advance.

\*\*\* Communications for the Journal to be addressed to the General Editor, DR. WILSON, University College, Toronto.

### NOTICE.

#### TO THE MEMBERS OF THE CANADIAN INSTITUTE.

As this number completes another volume of the Canadian Journal, Members of the Institute will please remember that the Annual Subscription (of &4 from members residing in Toronto and its vicinity, and &3 from country members,) falls due on the 1st of January, when the first number of the next volume will be issued.

Members whose former subscriptions remain unpaid, are particularly requested to remit them without delay, as by failing to do so they materially impede the progress of the Institute.

The Journal can only be continued in future to Members not in arrears.

CANADIAN INSTITUTE,

Toronto, November 1, 1857.
